Package ‘raster’

June 2, 2016

Type Package
Title Geographic Data Analysis and Modeling
Version 2.5-8
Date 2016-05-31
Depends methods, sp (>= 1.2-0), R (>= 3.0.0)
Suggests rgdal (>= 0.9-1), rgeos (>= 0.3-8), ncdf4, igraph, tcltk, parallel, rasterVis
LinkingTo Rcpp
Imports Rcpp
Description Reading, writing, manipulating, analyzing and modeling of gridded spatial data. The package implements basic and high-level functions. Processing of very large files is supported.
License GPL (>= 3)
URL http://cran.r-project.org/package=raster
ByteCompile TRUE
NeedsCompilation yes

Index ................ 230
Description

The raster package provides classes and functions to manipulate geographic (spatial) data in 'raster' format. Raster data divides space into cells (rectangles; pixels) of equal size (in units of the coordinate reference system). Such continuous spatial data are also referred to as 'grid' data, and be contrasted with discrete (object based) spatial data (points, lines, polygons).

The package should be particularly useful when using very large datasets that can not be loaded into the computer’s memory. Functions will work correctly, because they they process large files in chunks, i.e., they read, compute, and write blocks of data, without loading all values into memory at once.

Below is a list of some of the most important functions grouped by theme. See the vignette for more information and some examples (you can open it by running this command: vignette('Raster'))

Details

The package implements classes for Raster data (see Raster-class) and supports

- Creation of Raster* objects from scratch or from file
- Handling extremely large raster files
- Raster algebra and overlay functions
- Distance, neighborhood (focal) and patch functions
- Polygon, line and point to raster conversion
- Model predictions
- Summarizing raster values
- Easy access to raster cell-values
- Plotting (making maps)
- Manipulation of raster extent, resolution and origin
- Computation of row, col and cell numbers to coordinates and vice versa
- Reading and writing various raster file types

I. Creating Raster* objects

RasterLayer, RasterStack, and RasterBrick objects are, as a group, referred to as Raster* objects. Raster* objects can be created, from scratch, files, or from objects of other classes, with the following functions:

**raster**  
To create a RasterLayer

**stack**  
To create a RasterStack (multiple layers)

**brick**  
To create a RasterBrick (multiple layers)
### I. raster-package

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subset</td>
<td>Select layers of a RasterStack/Brick</td>
</tr>
<tr>
<td>addLayer</td>
<td>Add a layer to a Raster* object</td>
</tr>
<tr>
<td>dropLayer</td>
<td>Remove a layer from a RasterStack or RasterBrick</td>
</tr>
<tr>
<td>unstack</td>
<td>Create a list of RasterLayer objects from a RasterStack</td>
</tr>
</tbody>
</table>

### II. Changing the spatial extent and/or resolution of Raster* objects

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>merge</td>
<td>Combine Raster* objects with different extents (but same origin and resolution)</td>
</tr>
<tr>
<td>mosaic</td>
<td>Combine RasterLayers with different extents and a function for overlap areas</td>
</tr>
<tr>
<td>crop</td>
<td>Select a geographic subset of a Raster* object</td>
</tr>
<tr>
<td>extend</td>
<td>Enlarge a Raster* object</td>
</tr>
<tr>
<td>trim</td>
<td>Trim a Raster* object by removing exterior rows and/or columns that only have NAs</td>
</tr>
<tr>
<td>aggregate</td>
<td>Combine cells of a Raster* object to create larger cells</td>
</tr>
<tr>
<td>disaggregate</td>
<td>Subdivide cells</td>
</tr>
<tr>
<td>resample</td>
<td>Warp values to a Raster* object with a different origin or resolution</td>
</tr>
<tr>
<td>projectRaster</td>
<td>project values to a raster with a different coordinate reference system</td>
</tr>
<tr>
<td>shift</td>
<td>Move the location of Raster</td>
</tr>
<tr>
<td>flip</td>
<td>Flip values horizontally or vertically</td>
</tr>
<tr>
<td>rotate</td>
<td>Rotate values around the date-line (for lon/lat data)</td>
</tr>
<tr>
<td>t</td>
<td>Transpose a Raster* object</td>
</tr>
</tbody>
</table>

### III. Raster algebra

<table>
<thead>
<tr>
<th>Methods</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arith-methods</td>
<td>Arith functions (+, -, *, ^, %%, %/%, /)</td>
</tr>
<tr>
<td>Math-methods</td>
<td>Math functions like abs, sqrt, trunc, log, log10, exp, sin, round</td>
</tr>
<tr>
<td>Logic-methods</td>
<td>Logic functions (!, &amp;,</td>
</tr>
<tr>
<td>Summary-methods</td>
<td>Summary functions (mean, max, min, range, prod, sum, any, all)</td>
</tr>
<tr>
<td>Compare-methods</td>
<td>Compare functions (=, ! =, &gt;, &lt;, &lt;=, &gt;=)</td>
</tr>
</tbody>
</table>

### IV. Cell based computation

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>calc</td>
<td>Computations on a single Raster* object</td>
</tr>
<tr>
<td>overlay</td>
<td>Computations on multiple RasterLayer objects</td>
</tr>
<tr>
<td>cover</td>
<td>First layer covers second layer except where the first layer is NA</td>
</tr>
<tr>
<td>mask</td>
<td>Use values from first Raster except where cells of the mask Raster are NA</td>
</tr>
<tr>
<td>cut</td>
<td>Reclassify values using ranges</td>
</tr>
<tr>
<td>subs</td>
<td>Reclassify values using an 'is-becomes' matrix</td>
</tr>
</tbody>
</table>
V. Spatial contextual computation

- **distance**: Shortest distance to a cell that is not NA
- **gridDistance**: Distance when traversing grid cells that are not NA
- **distanceFromPoints**: Shortest distance to any point in a set of points
- **direction**: Direction (azimuth) to or from cells that are not NA
- **focal**: Focal (neighborhood; moving window) functions
- **localFun**: Local association (using neighborhoods) functions
- **boundaries**: Detection of boundaries (edges)
- **clump**: Find clumps (patches)
- **adjacent**: Identify cells that are adjacent to a set of cells on a raster
- **area**: Compute area of cells (for longitude/latitude data)
- **terrain**: Compute slope, aspect and other characteristics from elevation data
- **Moran**: Compute global or local Moran or Geary indices of spatial autocorrelation

VI. Model predictions

- **predict**: Predict a non-spatial model to a RasterLayer
- **interpolate**: Predict a spatial model to a RasterLayer

VII. Data type conversion

You can coerce Raster* objects to Spatial* objects using `as`, as in `as(object, 'SpatialGridDataFrame')`

- **raster**: RasterLayer from SpatialGrid*, image, or matrix objects
- **rasterize**: Rasterizing points, lines or polygons
- **rasterToPoints**: Create points from a RasterLayer
- **rasterToPolygons**: Create polygons from a RasterLayer
- **rasterToContour**: Contour lines from a RasterLayer
- **rasterFromXYZ**: RasterLayer from regularly spaced points
VIII. Summarizing

cellStats  Summarize a Raster cell values with a function
summary    Summary of the values of a Raster* object (quartiles and mean)
freq       Frequency table of Raster cell values
crosstab   Cross-tabulate two Raster* objects
unique     Get the unique values in a Raster* object
zonal      Summarize a Raster* object by zones in a RasterLayer

IX. Accessing values of Raster* object cells

Apart from the function listed below, you can also use indexing with [ for cell numbers, and [[] for row / column number combinations

getValues   Get all cell values (fails with very large rasters), or a row of values (safer)
getValuesBlock Get values for a block (a rectangular area)
getValuesFocal Get focal values for one or more rows
as.matrix   Get cell values as a matrix
as.array    Get cell values as an array
extract     Extract cell values from a Raster* object (e.g., by cell, coordinates, polygon)
sampleRandom Random sample
sampleRegular Regular sample
minValue     Get the minimum value of the cells of a Raster* object (not always known)
maxValue     Get the maximum value of the cells of a Raster* object (not always known)
setMinMax    Compute the minimum and maximum value of a Raster* object if these are not known

X. Plotting

See the rasterVis package for additional plotting methods for Raster* objects using methods from 'lattice' and other packages.

Maps
plot       Plot a Raster* object. The main method to create a map
plotRGB    Combine three layers (red, green, blue channels) into a single ‘real color’ image
spplot     Plot a Raster* with the spplot function (sp package)
image      Plot a Raster* with the image function
persp      Perspective plot of a RasterLayer
contour
filledContour
text

Interacting with a map
zoom
click
select
drawPoly
drawLine
drawExtent

Other plots
plot
hist
barplot
density
pairs
boxplot

XI. Getting and setting Raster* dimensions

Basic parameters of existing Raster* objects can be obtained, and in most cases changed. If there are values associated with a RasterLayer object (either in memory or via a link to a file) these are lost when you change the number of columns or rows or the resolution. This is not the case when the extent is changed (as the number of columns and rows will not be affected). Similarly, with projection you can set the projection, but this does not transform the data (see projectRaster for that).

ncol The number of columns
nrow The number of rows
ncell The number of cells (can not be set directly, only via ncol or nrow)
res The resolution (x and y)
nlayers How many layers does the object have?
names Get or set the layer names
xres The x resolution (can be set with res)
yres The y resolution (can be set with res)
xmin The minimum x coordinate (or longitude)
xmax The maximum x coordinate (or longitude)
ymin The minimum y coordinate (or latitude)
ymax The maximum y coordinate (or latitude)
extent The extent (minimum and maximum x and y coordinates)
origin The origin of a Raster* object
projection The coordinate reference system (map projection)
isLonLat Test if an object has a longitude/latitude coordinate reference system
filename Filename to which a RasterLayer or RasterBrick is linked
band layer (=band) of a multi-band file that this RasterLayer is linked to
nbands

How many bands (layers) does the file have?

compareRaster

Compare the geometry of Raster* objects

NAvalue

Get or set the NA value (for reading from a file)

XII. Computing row, column, cell numbers and coordinates

Cell numbers start at 1 in the upper-left corner. They increase within rows, from left to right, and then row by row from top to bottom. Likewise, row numbers start at 1 at the top of the raster, and column numbers start at 1 at the left side of the raster.

xFromCol  x-coordinates from column numbers
yFromRow  y-coordinates from row numbers
xFromCell  x-coordinates from row numbers
yFromCell  y-coordinates from cell numbers
xyFromCell  x and y coordinates from cell numbers
colFromX  Column numbers from x-coordinates (or longitude)
rowFromY  Row numbers from y-coordinates (or latitude)
rowColFromCell  Row and column numbers from cell numbers
cellFromXY  Cell numbers from x and y coordinates
cellFromRowCol  Cell numbers from row and column numbers
cellsFromExtent  Cell numbers from extent object
coordinates  x and y coordinates for all cells
validCell  Is this a valid cell number?
validCol  Is this a valid column number?
validRow  Is this a valid row number?

XIII. Writing files

Basic

setValues  Put new values in a Raster* object
writeRaster  Write all values of Raster* object to disk
KML  Save raster as KML file

Advanced

blockSize  Get suggested block size for reading and writing
writeStart  Open a file for writing
writeValues  Write some values
writeStop  Close the file after writing
update  Change the values of an existing file
XIV. Manipulation of SpatialPolygons* and other vector type Spatial* objects

Some of these functions are in the sp package. The name in bold is the equivalent command in ArcGIS. These functions build on the geometry ("spatial features") manipulation functions in package rgeos. These functions are extended here by also providing automated attribute data handling.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bind</td>
<td>append combine Spatial* objects of the same (vector) type</td>
</tr>
<tr>
<td>erase or &quot;-&quot;</td>
<td>erase parts of a SpatialPolygons* object</td>
</tr>
<tr>
<td>intersect or &quot;*&quot;</td>
<td>intersect SpatialPolygons* objects</td>
</tr>
<tr>
<td>union or &quot;+&quot;</td>
<td>union SpatialPolygons* objects</td>
</tr>
<tr>
<td>cover</td>
<td>update and identity a SpatialPolygons object with another one</td>
</tr>
<tr>
<td>symdif</td>
<td>symmetrical difference of two SpatialPolygons* objects</td>
</tr>
<tr>
<td>aggregate</td>
<td>dissolve smaller polygons into larger ones</td>
</tr>
<tr>
<td>disaggregate</td>
<td>explode: turn polygon parts into separate polygons (in the sp package)</td>
</tr>
<tr>
<td>crop</td>
<td>clip: a Spatial* object using a rectangle (Extent object)</td>
</tr>
<tr>
<td>select</td>
<td>select - interactively select spatial features</td>
</tr>
<tr>
<td>click</td>
<td>identify attributes by clicking on a map</td>
</tr>
<tr>
<td>merge</td>
<td>Join table (in the sp package)</td>
</tr>
<tr>
<td>over</td>
<td>spatial queries between Spatial* objects</td>
</tr>
<tr>
<td>extract</td>
<td>spatial queries between Spatial* and Raster* objects</td>
</tr>
<tr>
<td>as.data.frame</td>
<td>coerce coordinates of SpatialLines or SpatialPolygons into a data.frame</td>
</tr>
</tbody>
</table>

XV. Extent objects

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extent</td>
<td>Create an extent object</td>
</tr>
<tr>
<td>intersect</td>
<td>Intersect two extent objects</td>
</tr>
<tr>
<td>union</td>
<td>Combine two extent objects</td>
</tr>
<tr>
<td>round</td>
<td>round/floor/ceiling of the coordinates of an Extent object</td>
</tr>
<tr>
<td>alignExtent</td>
<td>Align an extent with a Raster* object</td>
</tr>
<tr>
<td>drawExtent</td>
<td>Create an Extent object by drawing it on top of a map (see plot)</td>
</tr>
</tbody>
</table>

XVI. Miscellaneous

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rasterOptions</td>
<td>Show, set, save or get session options</td>
</tr>
<tr>
<td>getData</td>
<td>Download and geographic data</td>
</tr>
<tr>
<td>pointDistance</td>
<td>Distance between points</td>
</tr>
<tr>
<td>readIniFile</td>
<td>Read a (windows) 'ini' file</td>
</tr>
<tr>
<td>hdr</td>
<td>Write header file for a number of raster formats</td>
</tr>
<tr>
<td>trim</td>
<td>Remove leading and trailing blanks from a character string</td>
</tr>
<tr>
<td>extension</td>
<td>Get or set the extension of a filename</td>
</tr>
<tr>
<td>cv</td>
<td>Coefficient of variation</td>
</tr>
<tr>
<td>modal</td>
<td>Modal value</td>
</tr>
</tbody>
</table>
addLayer

**sampleInt**
Random sample of (possibly very large) range of integer values

**showTmpFiles**
Show temporary files

**removeTmpFiles**
Remove temporary files

---

### XVII. For programmers

- **canProcessInMemory**
  Test whether a file can be created in memory

- **pbCreate**
  Initialize a progress bar

- **pbStep**
  Take a progress bar step

- **pbClose**
  Close a progress bar

- **readStart**
  Open file connections for efficient multi-chunk reading

- **readStop**
  Close file connections

- **rasterTmpFile**
  Get a name for a temporary file

- **inMemory**
  Are the cell values in memory?

- **fromDisk**
  Are the cell values read from a file?

---

### Acknowledgements

Extensive contributions were made by Jacob van Etten, Jonathan Greenberg, Matteo Mattiuzzi, and Michael Sumner. Significant help was also provided by Phil Heilman, Agustin Lobo, Oscar Perpinan Lamigueiro, Stefan Schlaffer, Jon Olav Skoien, Steven Mosher, and Kevin Ummel. Contributions were also made by Jochen Albrecht, Neil Best, Andrew Bevan, Roger Bivand, Isabelle Boulangeat, Lyndon Estes, Josh Gray, Tim Haering, Henry Herry, Paul Hiemstra, Ned Hornig, Mayeul Kauffmann, Bart Kranstauber, Rainer Krug, Alice Laborte, John Lewis, Lennon Li, Justin McGrath, Babak Naimi, Carsten Neumann, Joshua Perlman, Richard Plant, Edzer Pebesma, Etienne Racine, David Ramsey, Shaun Walbridge, Julian Zeidler and many others.

### Author(s)

Except where indicated otherwise, the functions in this package were written by Robert J. Hijmans

---

**addLayer**

**Add or drop a layer**

**Description**

Add a layer to a Raster* object or drop a layer from a RasterStack or RasterBrick. The object returned is always a RasterStack (unless nothing to add or drop was provided, in which case the original object is returned).
adjacent

Usage

```r
addLayer(x, ...)
dropLayer(x, i, ...)
```

Arguments

- `x` Raster* object
- `i` integer. Indices of the layers to be dropped
- `...` Additional arguments. The layers to add for `addLayer`. None for `dropLayer`.

Value

RasterStack

See Also

subset

Examples

```r
file <- system.file("external/test.grd", package="raster")
s <- stack(file, file, file)
r <- raster(file)
s <- addLayer(s, r/2, r*x2)
s
s <- dropLayer(s, c(3, 5))
nlayers(s)
```

---

**adjacent**

### Adjacent cells

**Description**

Identify cells that are adjacent to a set of cells on a raster.

**Usage**

```r
adjacent(x, cells, directions=4, pairs=TRUE, target=NULL, sorted=FALSE,
include=FALSE, id=FALSE)
```

**Arguments**

- `x` Raster* object
- `cells` vector of cell numbers for which adjacent cells should be found. Cell numbers start with 1 in the upper-left corner and increase from left to right and from top to bottom.
adjacent

directions the number of directions in which cells should be connected: 4 (rook’s case), 8 (queen’s case), 16 (knight and one-cell queen moves), or ‘bishop’ to connect cells with one-cell diagonal moves. Or a neighborhood matrix (see Details)
pairs logical. If TRUE, a matrix of pairs of adjacent cells is returned. If FALSE, a vector of cells adjacent to cells is returned
target optional vector of target cell numbers that should be considered. All other adjacent cells are ignored
sorted logical. Should the results be sorted?
include logical. Should the focal cells be included in the result?
id logical. Should the id of the cells be included in the result? (numbered from 1 to length(cells)

Details
A neighborhood matrix identifies the cells around each cell that are considered adjacent. The matrix should have one, and only one, cell with value 0 (the focal cell); at least one cell with value 1 (the adjacent cell(s)); All other cells are not considered adjacent and ignored.

Value
matrix or vector with adjacent cells.

Author(s)
Robert J. Hijmans and Jacob van Etten

Examples
r <- raster(nrows=10, ncols=10)
adjacent(r, cells=c(1, 55), directions=8, pairs=TRUE)

a <- adjacent(r, cell = c(1,55,90), directions=4, sorted=TRUE)
a

r[c(1,55,90)] <- 1
r[a] <- 2
plot(r)

# same result as above
rook <- matrix(c(NA, 1, NA,
1, 0, 1,
NA, 1, NA), ncol=3, byrow=TRUE)
adjacent(r, cells = c(1,55,90), directions=rook, sorted=TRUE)

# Count the number of times that a cell with a certain value
# occurs next to a cell with a certain value
set.seed(0)
r <- raster(ncol=10, nrow=10)
aggregate

Aggregate raster cells or SpatialPolygons/Lines

Description

Raster* objects:
Aggregate a Raster* object to create a new RasterLayer or RasterBrick with a lower resolution (larger cells). Aggregation groups rectangular areas to create larger cells. The value for the resulting cells is computed with a user-specified function.

SpatialPolygons:
Aggregate (‘dissolve’) SpatialPolygons, optionally by combining polygons that have the same attributes for one or more variables.

Usage

## S4 method for signature 'Raster'
aggregate(x, fact=2, fun=mean, expand=TRUE, na.rm=TRUE, filename='', ...)

## S4 method for signature 'SpatialPolygons'
aggregate(x, by, sums, dissolve=TRUE, vars=NULL, ...)

Arguments

x
  Raster* object or SpatialPolygons* object

fact
  integer. Aggregation factor expressed as number of cells in each direction (horizontally and vertically). Or two integers (horizontal and vertical aggregation factor) or three integers (when also aggregating over layers). See Details

fun
  function used to aggregate values

expand
  logical. If TRUE the output Raster* object will be larger then the input Raster* object if a division of the number of columns or rows with factor is not an integer

na.rm
  logical. If TRUE, NA cells are removed from calculations

filename
  character. Output filename (optional)

...  
  if x is a Raster* object, additional arguments as for writeRaster

by
  character or integer. The variables (column names or numbers) that should be used to aggregate (dissolve) the SpatialPolygons by only maintaining unique combinations of these variables. The default setting is to use no variables and aggregate all polygons. You can also supply a vector with a length of length(x)

r[] <- round(runif(ncell(r)) * 5)
a <- adjacent(r, 1:ncell(r), 4, pairs=TRUE)
tb <- table(r[a[,1]], r[a[,2]])
tb
  # make a matrix out of the 'table' object
tb <- unclass(tb)
plot(raster(tb, xmn=-0.5, xmx=5.5, ymn=-0.5, ymx=5.5))
suns list with function(s) and variable(s) to summarize. This should be a list of
lists in which each element of the main lists has two items. The first item
is function (e.g. mean), the second element is a vector of column names (or
indices) that need to summarize with that function. Be careful with charac-
ter and factor variables (you can use, e.g. 'first' function(x)x[1] or 'last'
function(x)x[length(x)] or modal for these variables
vars deprecated. Same as by
dissolve logical. If TRUE overlapping polygons are dissolved into single features (requires
package rgeos)

Details
Aggregation of a x will result in a Raster* object with fewer cells. The number of cells is the
number of cells of x divided by fact*fact (when fact is a single number) or prod(fact) (when
fact consists of 2 or 3 numbers). If necessary this number is adjusted according to the value of
expand. For example, fact=2 will result in a new Raster* object with 2*2=4 times fewer cells. If
two numbers are supplied, e.g., fact=c(2, 3), the first will be used for aggregating in the horizontal
direction, and the second for aggregating in the vertical direction, and the returned object will have
2*3=6 times fewer cells. Likewise, fact=c(2, 3, 4) aggregates cells in groups of 2 (rows) by 3
(columns) and 4 (layers).
Aggregation starts at the upper-left end of a raster (you can use flip if you want to start elsewhere).
If a division of the number of columns or rows with factor does not return an integer, the extent
of the resulting Raster object will either be somewhat smaller or somewhat larger then the original
RasterLayer. For example, if an input RasterLayer has 100 columns, and fact=12, the output Raster
object will have either 8 columns (expand=FALSE) (using 8 x 12 = 96 of the original columns)
or 9 columns (expand=TRUE). In both cases, the maximum x coordinate of the output RasterLayer
would, of course, also be adjusted.
The function fun should take multiple numbers, and return a single number. For example mean,
modal, min or max. It should also accept a na.rm argument (or ignore it as one of the 'dots' argu-
ments).

Value
RasterLayer or RasterBrick, or a SpatialPolygons* object

Author(s)
Robert J. Hijmans and Jacob van Etten

See Also
disaggregate, resample. For SpatialPolygons* disaggregate

Examples
r <- raster()
# a new aggregated raster, no values
ra <- aggregate(r, fact=10)
r <- setValues(r, runif(ncell(r)))
# a new aggregated raster, max of the values
ra <- aggregate(r, fact=10, fun=max)

# multiple layers
s <- stack(r, r*2)
x <- aggregate(s,2)

#SpatialPolygons
if (require(rgdal) & require(rgdal)) {
p <- shapefile(system.file("external/lux.shp", package="raster"))
p
pa0 <- aggregate(p)
p0
pa1 <- aggregate(p, by=NAME_1, sums=list(list(mean, 'ID_2')))
p0
pa1
}

alignExtent Align an extent (object of class Extent)

Description
Align an Extent object with the (boundaries of the) cells of a Raster* object

Usage
alignExtent(extent, object, snap='near')

Arguments
extent Extent object
object Raster* object
snap Character. One of 'near', 'in', or 'out', to determine in which direction the extent should be aligned. To the nearest border, inwards or outwards

Details
Aligning an Extent object to another object assures that it gets the same origin and resolution. This should only be used to adjust objects because of imprecision in the data. alignExtent should not be used to force data to match that really does not match (use e.g. resample or (dis)aggregate for this).

Value
Extent object

See Also
extent, drawExtent, Extent-class
animate

Examples

```r
r <- raster()
e <- extent(-10.1, 9.9, -20.1, 19.9)
ea <- alignExtent(e, r)
e
extent(r)
ea
```

---

**animate**  
*Animate layers of a Raster* object

**Description**

Animate (sequentially plot) the layers of a RasterStack or RasterBrick* object to create a movie.

**Usage**

```r
## S4 method for signature 'RasterStackBrick'
animate(x, pause=0.25, main, zlim, maxpixels=50000, n=10, ...)
```

**Arguments**

- **x**  
  Raster* object
- **pause**  
  numeric. How long should be the pause be between layers?
- **main**  
  title for each layer. If not supplied the z-value is used if available. Otherwise the names are used.
- **zlim**  
  numeric vector of length 2. Range of values to plot
- **maxpixels**  
  integer > 0. Maximum number of cells to use for the plot. If `maxpixels < ncell(x)`, `sampleRegular` is used before plotting
- **n**  
  integer > 0. Number of loops
- **...**  
  Additional arguments passed to `plot`

**Value**

None

**See Also**

`plot`, `spplot`, `plotRGB`

**Examples**

```r
b <- brick(system.file("external/rlogo.grd", package="raster"))
animate(b, n=1)
```
approxNA

Estimate values for cell values that are NA by interpolating between layers

Description

approxNA uses the stats function approx to estimate values for cells that are NA by interpolation across layers. Layers are considered equidistant, unless an argument 'z' is used, or getZ returns values, in which case these values are used to determine distance between layers.

For estimation based on neighbouring cells see focal

Usage

```r
## S4 method for signature 'RasterStackBrick'
approxNA(x, filename="", method="linear", yleft, yright,
         rule=1, f=0, ties=mean, z=NULL, NArule=1, ...)
```

Arguments

- `x` RasterStack or RasterBrick object
- `filename` character. Output filename (optional)
- `method` specifies the interpolation method to be used. Choices are "linear" or "constant" (step function; see the example in approx
- `yleft` the value to be returned before a non-NA value is encountered. The default is defined by the value of rule given below
- `yright` the value to be returned after the last non-NA value is encountered. The default is defined by the value of rule given below
- `rule` an integer (of length 1 or 2) describing how interpolation is to take place at for the first and last cells (before or after any non-NA values are encountered). If rule is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., rule = 2:1, if the left and right side extrapolation should differ
- `f` for method = "constant" a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If y0 and y1 are the values to the left and right of the point then the value is y0*(1-f)+y1*f so that f = 0) is right-continuous and f = 1 is left-continuous
- `ties` Handling of tied 'z' values. Either a function with a single vector argument returning a single number result or the string "ordered"
- `z` numeric vector to indicate the distance between layers (e.g., time, depth). The default is 1:nlayers(x)
- `NArule` single integer used to determine what to do when only a single layer with a non-NA value is encountered (and linear interpolation is not possible). The default value of 1 indicates that all layers will get this value for that cell; all other values do not change the cell values
- `...` additional arguments as for writeRaster
area

Value

RasterBrick

See Also

focal

Examples

```r
r <- raster(ncols=5, nrows=5)
r1 <- setValues(r, runif(ncell(r)))
r2 <- setValues(r, runif(ncell(r)))
r3 <- setValues(r, runif(ncell(r)))
r4 <- setValues(r, runif(ncell(r)))
r5 <- setValues(r, NA)
r6 <- setValues(r, runif(ncell(r)))
r1[6:10] <- NA
r2[5:15] <- NA
r3[8:25] <- NA
s <- stack(r1, r2, r3, r4, r5, r6)
s[1:5] <- NA
x1 <- approxNA(s)
x2 <- approxNA(s, rule=2)
x3 <- approxNA(s, rule=2, z=c(1,2,3,5,14,15))
```

<table>
<thead>
<tr>
<th>area</th>
<th>Size of cells</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

Compute the approximate surface area of cells in an unprojected (longitude/latitude) Raster object. It is an approximation because area is computed as the height (latitudinal span) of a cell (which is constant among all cells) times the width (longitudinal span) in the (latitudinal) middle of a cell. The width is smaller at the poleward side than at the equator-ward side of a cell. This variation is greatest near the poles and the values are thus not very precise for very high latitudes.

Usage

```r
## S4 method for signature 'RasterLayer'
area(x, filename="", na.rm=FALSE, weights=FALSE, ...)

## S4 method for signature 'RasterStackBrick'
area(x, filename="", na.rm=FALSE, weights=FALSE, ...)
```
### Arguments

- **x**: Raster* object
- **filename**: character. Filename for the output Raster object (optional)
- **na.rm**: logical. If TRUE, cells that are NA are ignored
- **weights**: logical. If TRUE, the area of each cells is divided by the total area of all cells that are not NA
- ... additional arguments as for `writeRaster`

### Details

If `x` is a RasterStack/Brick, a RasterBrick will be returned if `na.rm=TRUE`. However, if `na.rm=FALSE`, a RasterLayer is returned, because the values would be the same for all layers.

### Value

RasterLayer or RasterBrick. Cell values represent the size of the cell in km2, or the relative size if `weights=TRUE`

### Examples

```r
r <- raster(nrow=18, ncol=36)
a <- area(r)
```

### Description

Standard arithmetic operators for computations with Raster* objects and numeric values. The following operators are available: `+`, `-`, `*`, `/`, `^`, `%%`, `%/%`

The input Raster* objects should have the same extent, origin and resolution. If only the extent differs, the computation will continue for the intersection of the Raster objects. Operators are applied on a cell by cell basis. For a RasterLayer, numeric values are recycled by row. For a RasterStack or RasterBrick, recycling is done by layer. RasterLayer objects can be combined RasterStack/Brick objects, in which case the RasterLayer is 'recycled'. When using multiple RasterStack or RasterBrick objects, the number of layers of these objects needs to be the same.

In addition to arithmetic with Raster* objects, the following operations are supported for SpatialPolygons* objects. Given SpatialPolygon objects `x` and `y`:

- `x+y` is the same as `union(x, y)`. For SpatialLines* and SpatialPoints* it is equivalent to `bind(x, y)`
- `x*y` is the same as `intersect(x, y)`
- `x-y` is the same as `erase(x, y)`
**Details**

If the values of the output Raster* cannot be held in memory, they will be saved to a temporary file. You can use `options` to set the default file format, datatype and progress bar.

**Value**

A Raster* object, and in some cases the side effect of a new file on disk.

**See Also**

`Math-methods, overlay, calc`

**Examples**

```r
r1 <- raster(ncols=10, nrows=10)
r1[] <- runif(ncell(r1))
r2 <- setValues(r1, 1:ncell(r1) / ncell(r1) )
r3 <- r1 + r2
r2 <- r1 / 10
r3 <- r1 * (r2 - 1 + r1^2 / r2)

# recycling by row
r4 <- r1 * 0 + 1:ncol(r1)

# multi-layer object multiplication, no recycling
b1 <- brick(r1, r2, r3)
b2 <- b1 * 10

# recycling by layer
b3 <- b1 + c(1, 5, 10)

# addition of the cell-values of two RasterBrick objects
b3 <- b2 + b1

# summing two RasterBricks and one RasterLayer. The RasterLayer is 'recycled'
b3 <- b1 + b2 + r1
```

---

**as.data.frame**

Get a data.frame with raster cell values, or coerce SpatialPolygons, Lines, or Points to a data.frame

---

**Description**

`as.matrix` returns all values of a Raster* object as a matrix. For RasterLayers, rows and columns in the matrix represent rows and columns in the RasterLayer object. For other Raster* objects, the matrix returned by `as.matrix` has columns for each layer and rows for each cell.

`as.array` returns an array of matrices that are like those returned by `as.matrix` for a RasterLayer
If there is insufficient memory to load all values, you can use `getValues` or `getValuesBlock` to read chunks of the file. You could also first use `sampleRegular`.

The methods for Spatial* objects allow for easy creation of a data.frame with the coordinates and attributes; the default method only returns the attributes data.frame.

**Usage**

```r
## S4 method for signature 'Raster'
as.data.frame(x, row.names=NULL, optional=FALSE, xy=FALSE, 
               na.rm=FALSE, long=FALSE, ...)  
## S4 method for signature 'SpatialPolygons'
as.data.frame(x, row.names=NULL, optional=FALSE, 
               xy=TRUE, centroids=TRUE, sepNA=FALSE, ...) 
## S4 method for signature 'SpatialLines'
as.data.frame(x, row.names=NULL, optional=FALSE, 
               xy=FALSE, sepNA=FALSE, ...)  
```

**Arguments**

- `x`  
  Raster* object

- `row.names`  
  NULL or a character vector giving the row names for the data frame. Missing values are not allowed

- `optional`  
  logical. If TRUE, setting row names and converting column names (to syntactic names: see `make.names`) is optional

- `xy`  
  logical. If TRUE, also return the spatial coordinates

- `na.rm`  
  logical. If TRUE, remove rows with NA values. This can be particularly useful for very large datasets with many NA values

- `long`  
  logical. If TRUE, values are reshaped from a wide to a long format

- `centroids`  
  logical. If TRUE return the centroids instead of all spatial coordinates (only relevant if `xy=TRUE`)

- `sepNA`  
  logical. If TRUE the parts of the spatial objects are separated by lines that are NA (only if `xy=TRUE` and, for polygons, if `centroids=FALSE`)

- `...`  
  Additional arguments (none)

**Value**

data.frame

**Examples**

```r
r <- raster(ncol=3, nrow=3)  
r[] <- sqrt(1:ncell(r))  
r[3:5] <- NA  
as.data.frame(r)  
s <- stack(r, r*2)
```
as.data.frame(s)
as.data.frame(s, na.rm=TRUE)

as.list

Create a list of RasterLayer objects

Description

Create a list of RasterLayer objects from Raster* objects

Usage

## S4 method for signature 'Raster'
as.list(x, ...)

Arguments

x Raster* object

... additional Raster* objects

Value

list

Examples

r <- raster(ncol=3, nrow=3)
r[] <- 1:ncell(r)
as.list(r)

s <- stack(r,r*2,r*3)
as.list(s, r)

as.logical

Change cell values to logical or integer values

Description

Change values of a Raster* object to logical or integer values. With as.logical, zero becomes FALSE, all other values become TRUE. With as.integer values are truncated.

Usage

## S4 method for signature 'Raster'
as.logical(x, filename='', ...)

## S4 method for signature 'Raster'
as.integer(x, filename='', ...)

as.logical(x, filename='', ...)
Arguments

- **x**: Raster* object
- **filename**: character. Output filename (optional)
- ... additional optional arguments as for `writeRaster`

See Also

- `as.logical`, `as.integer`

Examples

```r
r <- raster(nrow=10, ncol=10)
set.seed(0)
r[] <- runif(ncell(r)) * 10
r
r <- as.integer(r)
r
as.logical(r)
```

Description

`as.vector` returns a vector of cell values. For a RasterLayer it is equivalent to `getValues(x)`.

`as.matrix` returns all values of a Raster* object as a matrix. For RasterLayers, rows and columns in the matrix represent rows and columns in the RasterLayer object. For other Raster* objects, the matrix returned by `as.matrix` has columns for each layer and rows for each cell.

`as.array` returns an array of matrices that are like those returned by `as.matrix` for a RasterLayer.

If there is insufficient memory to load all values, you can use `getValues` or `getValuesBlock` to read chunks of the file.

`as.matrix` and `as.vector` can also be used to obtain the coordinates from an Extent object.

Usage

```r
as.matrix(x, ...)
as.array(x, ...)
```

```r
## S4 method for signature 'Extent'
as.vector(x, mode='any')
```

```r
## S4 method for signature 'Raster'
as.vector(x, mode='any')
```
as.raster

Arguments

x Raster* or (for as.matrix and as.vector) Extent object
mode Character string giving an atomic mode (such as "numeric" or "character") or "list", or "any". Note: this argument is currently ignored!

additional arguments:
maxpixels Integer. To regularly subsample very large objects
transpose Logical. Transpose the data? (for as.array only)

Value

matrix, array, or vector

Examples

r <- raster(ncol=3, nrow=3)
r[] <- 1:necell(r)
as.matrix(r)
s <- stack(r,r)
as.array(s)
as.vector(extent(s))

as.raster Coerce to a 'raster' object

Description

Implementation of the generic as.raster function to create a 'raster' (small r) object. NOT TO BE CONFUSED with the Raster* (big R) objects defined by the raster package! Such objects can be used for plotting with the rasterImage function.

Usage

as.raster(x, ...)

Arguments

x RasterLayer object

... Additional arguments.
maxpixels Integer. To regularly subsample very large objects
col Vector of colors. Default is col=rev(terrain.colors(255)))

Value

'Raster' object
Examples

```r
r <- raster(ncol=3, nrow=3)
r[] <- 1:ncell(r)
as.raster(r)
```

---

atan2

Two argument arc-tangent

---

Description

For Raster* objects `x` and `y`, atan2(y, x) returns the angle in radians for the tangent `y/x`, handling the case when `x` is zero. See Trig

See Math-methods for other trigonometric and mathematical functions that can be used with Raster* objects.

Usage

```r
atan2(y, x)
```

Arguments

- `y` Raster* object
- `x` Raster* object

See Also

Math-methods

Examples

```r
r1 <- r2 <- raster(nrow=10, ncol=10)
r1[] <- (runif(ncell(r1))<0.5) * 10
r2[] <- (runif(ncell(r1))<0.5) * 10
atan2(r1, r2)
```
**Description**

Compute Moran’s I or Geary’s C measures of global spatial autocorrelation in a RasterLayer, or compute the local Moran or Geary index (Anselin, 1995).

**Usage**

```r
Geary(x, w = matrix(c(1, 1, 1, 0, 1, 1, 1), 3, 3))
Moran(x, w = matrix(c(1, 1, 1, 0, 1, 1, 1), 3, 3))
MoranLocal(x, w = matrix(c(1, 1, 1, 0, 1, 1, 1), 3, 3))
GearyLocal(x, w = matrix(c(1, 1, 1, 0, 1, 1, 1), 3, 3))
```

**Arguments**

- `x` RasterLayer
- `w` Spatial weights defined by or a rectangular matrix with odd length (3, 5, ...) sides (as in `focal`)

**Details**

The default setting uses a 3x3 neighborhood to compute "Queen’s case" indices. You can use a filter (weights matrix) to do other things, such as "Rook’s case", or different lags.

**Value**

A single value (Moran’s I or Geary’s C) or a RasterLayer (Local Moran or Geary values)

**Author(s)**

Robert J. Hijmans and Babak Naimi

Examples

```r
r <- raster(nrows=10, ncols=10)
r[] <- 1:ncell(r)

Moran(r)
# Rook's case
f <- matrix(c(0,1,0,1,0,1,0,1,0,0,1,0,1,0,1,0), nrow=3)
Moran(r, f)

Geary(r)

x1 <- MoranLocal(r)
# Rook's case
x2 <- MoranLocal(r, w=f)
```

<table>
<thead>
<tr>
<th>bands</th>
<th>Number of bands</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

A ‘band’ refers to a single layer for a possibly multi-layer file. Most RasterLayer objects will refer to files with a single layer. The term ‘band’ is frequently used in remote sensing to refer to a variable (layer) in a multi-variable dataset as these variables typically represent reflection in different bandwidths in the electromagnetic spectrum. But in that context, bands could be stored in a single or in separate files. In the context of the raster package, the term band is equivalent to a layer in a raster file.
	nbands returns the number of bands of the file that a RasterLayer points to (and 1 if it does not point at any file). This function also works for a RasterStack for which it is equivalent to nlayers.

band returns the specific band the RasterLayer refers to (1 if the RasterLayer points at single layer file or does not point at any file).

Usage

```r
nbands(x)
bandnr(x, ...)
```

Arguments

- `x` RasterLayer
- `...` Additional arguments (none at this time)

Value

numeric >= 1
barplot

See Also

nlayers

Examples

```r
f <- system.file("external/rlogo.grd", package="raster")
r <- raster(f, layer=2)
nbands(r)
bandnr(r)
```

---

### Description

Create a barplot of the values of a RasterLayer. For large datasets a regular sample with a size of approximately `maxpixels` is used.

### Usage

```r
## S4 method for signature 'RasterLayer'
barplot(height, maxpixels=1000000, digits=0, breaks=NULL, col=rainbow, ...)
```

### Arguments

- `height` - RasterLayer
- `maxpixels` - integer. To regularly subsample very large objects
- `digits` - integer used to determine how to round the values before tabulating. Set to NULL or to a large number if you do not want any rounding
- `breaks` - breaks used to group the data as in `cut`
- `col` - a color generating function such as `rainbow`, or a vector of colors
- `...` - additional arguments for plotting as in `barplot`

### Value

A numeric vector (or matrix, when `beside` = `TRUE`) of the coordinates of the bar midpoints, useful for adding to the graph. See `barplot`

### See Also

`hist`, `boxplot`
Examples

```
f <- system.file("external/test.grd", package="raster")
r <- raster(f)
barplot(r, digits=-2, las=2, ylab='Frequency')

op <- par(no.readonly = TRUE)
par(mai = c(1, 2,.5,.5))
barplot(r, breaks=10, col=c('red', 'blue'), horiz=TRUE, digits=NULL, las=1)
par(op)
```

## bind

**Bind Spatial* objects**

Bind (append) Spatial* objects into a single object. All objects must be of the same vector type base class (SpatialPoints, SpatialLines, or SpatialPolygons)

### Usage

```
## S4 method for signature 'SpatialPolygons, SpatialPolygons'
bind(x, y, ..., keepnames=FALSE)

## S4 method for signature 'SpatialLines, SpatialLines'
bind(x, y, ..., keepnames=FALSE)

## S4 method for signature 'SpatialPoints, SpatialPoints'
bind(x, y, ..., keepnames=FALSE)

## S4 method for signature 'data.frame, data.frame'
bind(x, y, ..., variables=NULL)
```

### Arguments

- `x`: Spatial* object or data.frame
- `y`: Spatial* object or data.frame
- `...`: Additional Spatial* objects
- `keepnames`: Logical. If TRUE the row.names are kept (if unique)
- `variables`: character. Variable (column) names to keep. If NULL, all variables are kept

### Value

Spatial* object
blockSize

See Also

merge

Examples

```r
if (require(rgdal) & require(rgeos)) {
  p <- shapefile(system.file("external/lux.shp", package="raster"))
  mersch <- p[p$NAME_2=='Mersch', ]
  diekirch <- p[p$NAME_2=='Diekirch', ]
  remich <- p[p$NAME_2=='Remich', ]
  remich$NAME_1 <- NULL
  x <- bind(mersch, diekirch, remich)
  plot(x)
  data.frame(x)
}
```

blockSize

### Block size for writing files

#### Description

This function can be used to suggest chunk sizes (always a number of entire rows), and corresponding row numbers, to be used when processing Raster* objects in chunks. Normally used together with `writeValues`.

#### Usage

```
blockSize(x, chunksize, n=nlayers(x), minblocks=4, minrows=1)
```

#### Arguments

- **x** Raster* object
- **chunksize** Integer, normally missing. Can be used to set the block size; unit is number of cells. Block size is then computed in units of number of rows (always >= 1)
- **n** Integer. Number of layers to consider. The function divides chunksize by n to determine blocksize
- **minblocks** Integer. Minimum number of blocks
- **minrows** Integer. Minimum number of rows in each block

#### Value

A list with three elements:

- **rows**, the suggested row numbers at which to start the blocks for reading and writing,
- **nrows**, the number of rows in each block, and,
- **n**, the total number of blocks
See Also

writeValues

Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
blockSize(r)
```

---

**boundaries (edges) detection**

**Description**

Detect boundaries (edges). Boundaries are cells that have more than one class in the 4 or 8 cells surrounding it, or, if `classes`=FALSE, cells with values and cells with NA.

**Usage**

```r
## S4 method for signature 'RasterLayer'
boundaries(x, type='inner', classes=FALSE, directions=8, asNA=FALSE, filename="", ...)  
```

**Arguments**

- `x` RasterLayer object
- `type` character. 'inner' or 'outer'
- `classes` character. Logical. If TRUE all different values are (after rounding) distinguished, as well as NA. If FALSE (the default) only edges between NA and non-NA cells are considered
- `directions` integer. Which cells are considered adjacent? Should be 8 (Queen's case) or 4 (Rook's case)
- `asNA` logical. If TRUE, non-edges are returned as NA instead of zero
- `filename` character. Filename for the output RasterLayer (optional)
- `...` additional arguments as for `writeRaster`

**Value**

RasterLayer. Cell values are either 1 (a border) or 0 (not a border), or NA

**Note**

'edge' is obsolete and should not be used. It will be removed from this package

**See Also**

focal, clump
### Examples

```r
r <- raster(nrow=18, ncol=36, xmin=0)
r[150:250] <- 1
r[251:450] <- 2
plot( boundaries(r, type='inner') )
plot( boundaries(r, type='outer') )
plot( boundaries(r, classes=TRUE) )
```

---

### Description

Box plot of layers in a Raster object

### Usage

```r
## S4 method for signature 'RasterStackBrick'
boxplot(x, maxpixels=100000, ...)

## S4 method for signature 'RasterLayer'
boxplot(x, y=NULL, maxpixels=100000, ...)
```

### Arguments

- `x`  
  Raster* object

- `y`  
  If `x` is a RasterLayer object, `y` can be an additional RasterLayer to group the values of `x` by 'zone'

- `maxpixels`  
  Integer. Number of pixels to sample from each layer of large Raster objects

- `...`  
  Arguments passed to `graphics::boxplot`

### See Also

`pairs`, `hist`

### Examples

```r
r1 <- r2 <- r3 <- raster(ncol=10, nrow=10)
r1[] <- rnorm(nCELL(r1), 100, 40)
r2[] <- rnorm(nCELL(r1), 80, 10)
r3[] <- rnorm(nCELL(r1), 120, 30)
s <- stack(r1, r2, r3)
names(s) <- c('A', 'B', 'C')

boxplot(s, notch=TRUE, col=c('red', 'blue', 'orange'), main='Box plot', ylab='random')
```
Create a RasterBrick object

Description

A RasterBrick is a multi-layer raster object. They are typically created from a multi-layer (band) file; but they can also exist entirely in memory. They are similar to a RasterStack (that can be created with `stack`), but processing time should be shorter when using a RasterBrick. Yet they are less flexible as they can only point to a single file.

A RasterBrick can be created from RasterLayer objects, from a RasterStack, or from a (multi-layer) file. The can also be created from SpatialPixels*, SpatialGrid*, and Extent objects, and from a three-dimensional array.

Usage

```r
## S4 method for signature 'character'
brick(x, ...)

## S4 method for signature 'RasterStack'
brick(x, values=TRUE, nl, filename='', ...)

## S4 method for signature 'RasterBrick'
brick(x, nl, ...)

## S4 method for signature 'RasterLayer'
brick(x, ..., values=TRUE, nl=1, filename='')

## S4 method for signature 'missing'
brick(nrows=180, ncols=360, xmn=-180, xmx=180, ymn=-90, ymx=90, nl=1, crs)

## S4 method for signature 'Extent'
brick(x, nrows=10, ncols=10, crs=NA, nl=1)

## S4 method for signature 'array'
brick(x, xmn=0, xmx=1, ymn=0, ymx=1, crs=NA, transpose=FALSE)

## S4 method for signature 'big.matrix'
brick(x, template, filename='', ...)

## S4 method for signature 'SpatialGrid'
brick(x)

## S4 method for signature 'SpatialPixels'
brick(x)
```
Arguments

- **x**: character (filename, see Details); Raster* object; missing; array; SpatialGrid*; SpatialPixels*; Extent; or list of Raster* objects. Supported file types are the 'native' raster package format and those that can be read via rgdal (see `readGDAL`), and NetCDF files (see details).

- **values**: logical. If TRUE, the cell values of 'x' are copied to the RasterBrick object that is returned.

- **nl**: integer > 0. How many layers should the RasterBrick have?

- **filename**: character. Filename if you want the RasterBrick to be saved on disk.

- **nrows**: integer > 0. Number of rows.

- **ncols**: integer > 0. Number of columns.

- **xmn**: minimum x coordinate (left border).

- **xmx**: maximum x coordinate (right border).

- **ymn**: minimum y coordinate (bottom border).

- **ymx**: maximum y coordinate (top border).

- **crs**: character or object of class CRS. PROJ4 type description of a Coordinate Reference System (map projection). If this argument is missing, and the x coordinates are withing -360 .. 360 and the y coordinates are within -90 .. 90, "+proj=longlat +datum=WGS84" is used.

- **transpose**: if TRUE, the values in the array are transposed.

- **template**: Raster* object used to set the extent, number of rows and columns and CRS.

Details

If x is a RasterLayer, the additional arguments can be used to pass additional Raster* objects.

If there is a filename argument, the additional arguments are as for `writeRaster`. The big.matrix must have rows representing cells and columns representing layers.

If x represents a filename there is the following additional argument:

- **native**: logical. If TRUE (not the default), reading and writing of IDRISI, BIL, BSQ, BIP, and Arc ASCII files is done with native (raster package) drivers, rather then via rgdal.

In addition, if x is a NetCDF filename there are the following additional arguments:

- **varname**: character. The variable name (e.g. 'altitude' or 'precipitation'. If not supplied and the file has multiple variables are a guess will be made (and reported))

- **lvar**: integer > 0 (default=3). To select the 'level variable' (3rd dimension variable) to use, if the file has 4 dimensions (e.g. depth instead of time)

- **level**: integer > 0 (default=1). To select the 'level’ (4th dimension variable) to use, if the file has 4 dimensions, e.g. to create a RasterBrick of weather over time at a certain height.

To use NetCDF files the `ncdf4` package needs to be available. It is assumed that these files follow, or are compatible with the CF-1 convention.
Value

RasterBrick

See Also

raster

Examples

b <- brick(system.file("external/rlogo.grd", package="raster"))
b
nlayers(b)
names(b)
eextract(b, 870)

Description

Calculate a buffer around all cells that are not NA.

Note that the distance unit of the buffer width parameter is meters if the RasterLayer is not projected (+proj=longlat), and in map units (typically also meters) when it is projected.

Usage

## S4 method for signature 'RasterLayer'
buffer(x, width=0, filename='', doEdge=FALSE, ...)

## S4 method for signature 'Spatial'
buffer(x, width=1, dissolve=TRUE, ...)

Arguments

x  RasterLayer or Spatial* object
width  numeric > 0. Unit is meter if x has a longitude/latitude CRS, or mapunits in other cases
filename  character. Filename for the output RasterLayer (optional)
doEdge  logical. If TRUE, the boundaries function is called first. This may be efficient in cases where you compute a buffer around very large areas because boundaries determines the edge cells that matter for distance computation
dissolve  logical. If TRUE, buffer geometries of overlapping polygons are dissolved and all geometries are aggregated and attributes (the data.frame) are dropped
...
  Additional arguments as for writeRaster
calc

Value

RasterLayer or SpatialPolygons* object

See Also

distance, gridDistance, pointDistance

Examples

```r
r <- raster(ncol=36, nrow=18)
r[] <- NA
r[500] <- 1
b <- buffer(r, width=5000000)
#plot(b)
```

Description

Calculate values for a new Raster* object from another Raster* object, using a formula.

If `x` is a RasterLayer, `fun` is typically a function that can take a single vector as input, and return a vector of values of the same length (e.g. `sqrt`). If `x` is a RasterStack or RasterBrick, `fun` should operate on a vector of values (one vector for each cell). `calc` returns a RasterLayer if `fun` returns a single value (e.g. `sum`) and it returns a RasterBrick if `fun` returns more than one number, e.g., `fun=quantile`.

In many cases, what can be achieved with `calc`, can also be accomplished with a more intuitive ‘raster-algebra’ notation (see Arith-methods). For example, `r <- r * 2` instead of `r <- calc(r, fun=function(x){x * 2})`, or `r <- sum(s)` instead of `r <- calc(s, fun=sum)`. However, `calc` should be faster when using complex formulas on large datasets. With `calc` it is possible to set an output filename and file type preferences.

See (overlay) to use functions that refer to specific layers, like `(function(a,b,c){a + sqrt(b) / c})`

Usage

```r
## S4 method for signature 'Raster,function'
calc(x, fun, filename='', na.rm, forcefun=FALSE, forceapply=FALSE, ...)
```

Arguments

- `x` Raster* object
- `fun` function
- `filename` character. Output filename (optional)
- `na.rm` Remove NA values, if supported by ‘fun’ (only relevant when summarizing a multilayer Raster object into a RasterLayer)
**forcefun**

logical. Force `calc` to not use `fun` with `apply` for use with ambiguous functions and for debugging (see Details)

**forceapply**

logical. Force `calc` to use `fun` with `apply` for use with ambiguous functions and for debugging (see Details)

... Additional arguments as for `writeRaster`

**Details**

The intent of some functions can be ambiguous. Consider:

```r
library(raster)

r <- raster(volcano)
calc(r, function(x) x * 1:10)
```

In this case, the cell values are multiplied in a vectorized manner and a single layer is returned where the first cell has been multiplied with one, the second cell with two, the 11th cell with one again, and so on. But perhaps the intent was to create 10 new layers (x*1, x*2, ...)? This can be achieved by using argument `forceapply=TRUE`

```r
calc(r, function(x) x * 1:10), forceapply=TRUE
```

**Value**

a Raster* object

**Note**

For large objects `calc` will compute values chunk by chunk. This means that for the result of `fun` to be correct it should not depend on having access to _all_ values at once. For example, to scale the values of a Raster* object by subtracting its mean value (for each layer), you would _not_ do, for Raster object `x`:

```r
calc(x, function(x)scale(x, scale=FALSE))
```

Because the mean value of each chunk will likely be different. Rather do something like

```r
m <- cellStats(x, 'mean')
x <- m
```

**Author(s)**

`overlay`, `reclassify`, `Arith-methods`, `Math-methods`
Examples

```r
r <- raster(ncols=36, nrows=18)
r[] <- 1:ncell(r)

# multiply values with 10
fun <- function(x) { x * 10 }
rc1 <- calc(r, fun)

# set values below 100 to NA.
fun <- function(x) { x[x<100] <- NA; return(x) }
rc2 <- calc(r, fun)

# set NA values to -9999
fun <- function(x) { x[is.na(x)] <- -9999; return(x) }
rc3 <- calc(rc2, fun)

# using a RasterStack as input
s <- stack(r, r*2, sqrt(r))
# return a RasterLayer
rs1 <- calc(s, sum)

# return a RasterBrick
rs2 <- calc(s, fun=function(x) x * 10)
# recycling by layer
rs3 <- calc(s, fun=function(x) x * c(1, 5, 10))

# use overlay when you want to refer to individual layer in the function
# but it can be done with calc:
rs4 <- calc(s, fun=function(x) x[1]*x[2]*x[3])

##
## Some regression examples
##

# create data
r <- raster(nrow=10, ncol=10)
s1 <- lapply(1:12, function(i) setValues(r, rnorm(ncell(r), i, 3)))
s2 <- lapply(1:12, function(i) setValues(r, rnorm(ncell(r), i, 3)))
s1 <- stack(s1)
s2 <- stack(s2)

# regression of values in one brick (or stack) with another
s <- stack(s1, s2)
# s1 and s2 have 12 layers; coefficients[2] is the slope
x1 <- calc(s, fun)

# regression of values in one brick (or stack) with 'time'
time <- 1:nlayers(s)
fun <- function(x) { lm(x ~ time)$coefficients[2] }
x2 <- calc(s, fun)
```
Get cell number(s) of a Raster* object from row and/or column numbers. Cell numbers start at 1 in the upper left corner, and increase from left to right, and then from top to bottom. The last cell number equals the number of cells of the Raster* object.

Usage

cellFrom(object, rownr, colnr)
cellFromRowColCombine(object, rownr, colnr)
cellFromRowCol(object, rownr, colnr)
cellFromRow(object, rownr)
cellFromCol(object, colnr)
colFromX(object, x)
rowFromY(object, y)
cellFromXY(object, xy)
cellFromLine(object, lns)
cellFromPolygon(object, p, weights=FALSE)
fourCellsFromXY(object, xy, duplicates=TRUE)

Arguments

object Raster* object (or a SpatialPixels* or SpatialGrid* object)
colnr column number; or vector of column numbers
rownr row number; or vector of row numbers
x x coordinate(s)
y y coordinate(s)
cellFrom

xy matrix of x and y coordinates, or a SpatialPoints or SpatialPointsDataFrame object

lns SpatialLines object

p SpatialPolygons object

weights Logical. If TRUE, the fraction of each cell that is covered is also returned

duplicates Logical. If TRUE, the same cell number can be returned twice (if the point in the middle of a division between two cells) or four times (if a point is in the center of a cell)

Details
cellFromRowCol returns the cell numbers obtained for each row / col number pair. In contrast, cellFromRowColCombine returns the cell numbers obtained by the combination of all row and column numbers supplied as arguments.
fourCellsFromXY returns the four cells that are nearest to a point (if the point falls on the raster). Also see adjacent.

Value
vector of row, column or cell numbers. cellFromLine and cellFromPolygon return a list, fourCellsFromXY returns a matrix.

See Also
xyFromCell, cellsFromExtent, rowColFromCell

Examples
r <- raster(ncol=10, nrow=10)
cellFromRowCol(r, 5, 5)
cellFromRowCol(r, 1:2, 1:2)
cellFromRowColCombine(r, 1:3, 1:2)
cellFromCol(r, 1)
cellFromRow(r, 1)

colFromX(r, 0.5)
rowFromY(r, 0.5)
cellFromXY(r, cbind(c(0.5,5), c(15, 88)))
fourCellsFromXY(r, cbind(c(0.5,5), c(15, 88)))

cds1 <- rbind(c(-180,-20), c(-180,5), c(-60, 0), c(-160,-60), c(-180,-20))
cds2 <- rbind(c(80,0), c(100,60), c(120,0), c(120,55), c(80,0))
pols <- SpatialPolygons(list(Polygons(list(Polygon(cds1)), 1), Polygons(list(Polygon(cds2)), 2)))
cellFromPolygon(r, pols)
cellsFromExtent  Cells from Extent

Description

This function returns the cell numbers for a Raster* object that are within a specified extent (rectangular area), supply an object of class Extent, or another Raster* object.

Usage

cellsFromExtent(object, extent, expand=FALSE)

Arguments

object  A Raster* object
extent  An object of class Extent (which you can create with newExtent(), or another Raster* object)
expand  Logical. If TRUE, NA is returned for (virtual) cells implied by bndbox, that are outside the RasterLayer (object). If FALSE, only cell numbers for the area where object and bndbox overlap are returned (see intersect)

Value

a vector of cell numbers

See Also

extent, cellFromXY

Examples

r <- raster()
bb <- extent(-5, 5, -5, 5)
cells <- cellsFromExtent(r, bb)
r <- crop(r, bb)
r[] <- cells
cellStats  Statistics across cells

Description

Compute statistics for the cells of each layer of a Raster* object. In the raster package, functions such as max, min, and mean, when used with Raster* objects as argument, return a new Raster* object (with a value computed for each cell). In contrast, cellStats returns a single value, computed from all the values of a layer. Also see layerStats

Usage

```r
## S4 method for signature 'RasterLayer'
cellStats(x, stat='mean', na.rm=TRUE, asSample=TRUE, ...)
```

```
## S4 method for signature 'RasterStackBrick'
cellStats(x, stat='mean', na.rm=TRUE, asSample=TRUE, ...)
```

Arguments

- `x`: Raster* object
- `stat`: The function to be applied. See Details
- `na.rm`: Logical. Should NA values be removed?
- `asSample`: Logical. Only relevant for `stat=sd` in which case, if TRUE, the standard deviation for a sample (denominator is n-1) is computed, rather than for the population (denominator is n)
- `...`: Additional arguments

Details

cellStats will fail (gracefully) for very large Raster* objects except for a number of known functions: sum, mean, min, max, sd, 'skew' and 'rms'. 'skew' (skewness) and 'rms' (Root Mean Square) must be supplied as a character value (with quotes), the other known functions may be supplied with or without quotes. For other functions you could perhaps use a sample of the RasterLayer that can be held in memory (see sampleRegular)

Value

Numeric

See Also

freq, quantile, minValue, maxValue, setMinMax
Examples

```r
r <- raster(nrow=18, ncol=36)
r[] <- runif(ncell(r)) * 10
# works for large files
cellStats(r, 'mean')
# same, but does not work for very large files
cellStats(r, mean)
# multi-layer object
cellStats(brick(r, r), mean)
```

clamp

**Clamp values**

Description

Clamp values to a minimum and maximum value. That is, all values below the lower clamp value and the upper clamp value become NA (or the lower/upper value if useValue=TRUE)

Usage

```r
## S4 method for signature 'Raster'
clamp(x, lower=-Inf, upper=Inf, useValues=TRUE, filename='', ...)  
```

Arguments

- `x` RasterLayer, or numeric vector
- `lower` numeric. lowest value
- `upper` numeric. highest value
- `useValues` logical. If FALSE values outside the clamping range become NA, if TRUE, they get the extreme values
- `filename` character. Filename for the output RasterLayer (optional)
- `...` additional arguments as for `writeRaster`

Value

Raster object

See Also

`reclassify`

Examples

```r
r <- raster(ncols=12, nrows=12)
values(r) <- 1:ncell(r)
rc <- clamp(r, 25, 75)
rc
```
clearValues

### Description
Clear cell values of a Raster* object from memory

### Usage
```r
clearValues(x)
```

### Arguments
- `x`: Raster* object

### Value
a Raster* object

### See Also
- `values`, `replacement`

### Examples
```r
r <- raster(ncol=10, nrow=10)
r[] <- 1:ncell(r)
r <- clearValues(r)
```

---

### click
Query by clicking on a map

### Description
Click on a map (plot) to get values of a Raster* or Spatial* object at that location; and optionally the coordinates and cell number of the location. For SpatialLines and SpatialPoints you need to click twice (draw a box).
Usage

```r
## S4 method for signature 'Raster'
click(x, n=Inf, id=FALSE, xy=FALSE, cell=FALSE, type="n", show=TRUE, ...)

## S4 method for signature 'SpatialGrid'
click(x, n=1, id=FALSE, xy=FALSE, cell=FALSE, type="n", ...)

## S4 method for signature 'SpatialPolygons'
click(x, n=1, id=FALSE, xy=FALSE, type="n", ...)

## S4 method for signature 'SpatialLines'
click(x, ...)

## S4 method for signature 'SpatialPoints'
click(x, ...)
```

Arguments

- `x`: Raster*, or Spatial* object (or missing)
- `n`: number of clicks on the map
- `id`: Logical. If TRUE, a numeric ID is shown on the map that corresponds to the row number of the output
- `xy`: Logical. If TRUE, xy coordinates are included in the output
- `cell`: Logical. If TRUE, cell numbers are included in the output
- `type`: One of "n", "p", "l" or "o". If "p" or "o" the points are plotted; if "l" or "o" they are joined by lines. See ?locator
- `show`: logical. Print the values after each click?
- `...`: additional graphics parameters used if type != "n" for plotting the locations. See ?locator

Value

The value(s) of `x` at the point(s) clicked on (or touched by the box drawn).

Note

The plot only provides the coordinates for a spatial query, the values are read from the Raster* or Spatial* object that is passed as an argument. Thus you can extract values from an object that has not been plotted, as long as it spatially overlaps with the extent of the plot.

Unless the process is terminated prematurely values at at most n positions are determined. The identification process can be terminated by clicking the second mouse button and selecting 'Stop' from the menu, or from the 'Stop' menu on the graphics window.

See Also

`select`, `drawExtent`
Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
#plot(r)
#click(r)
#now click on the plot (map)
```

---

**Description**

Detect clumps (patches) of connected cells. Each clump gets a unique ID. NA and zero are used as background values (i.e. these values are used to separate clumps). You can use queen’s or rook’s case, using the directions argument. For larger files that are processed in chunks, the highest clump number is not necessarily equal to the number of clumps (unless you use argument gaps=FALSE).

**Usage**

```r
## S4 method for signature 'RasterLayer'
clump(x, filename="", directions=8, gaps=TRUE, ...)
```

**Arguments**

- `x`: RasterLayer
- `filename`: Character. Filename for the output RasterLayer (optional)
- `directions`: Integer. Which cells are considered adjacent? Should be 8 (Queen’s case) or 4 (Rook’s case)
- `gaps`: Logical. If TRUE (the default), there may be ‘gaps’ in the chunk numbers (e.g. you may have clumps with IDs 1, 2, 3 and 5, but not 4). If it is FALSE, these numbers will be recoded from 1 to n (4 in this example)
- `...`: Additional arguments as for `writeraster`

**Value**

RasterLayer

**Note**

This function requires that the igraph package is available.

**Author(s)**

Robert J. Hijmans and Jacob van Etten
cluster

Examples

```
r <- raster(ncols=12, nrows=12)
set.seed(0)
r[] <- round(runif(ncell(r))*0.7 )
rc <- clump(r)
freq(rc)
plot(rc)
```

Description

beginCluster creates, and endCluster deletes a 'snow' cluster object. This object can be used for multi-core computing with those 'raster' functions that support it.

beginCluster determines the number of nodes (cores) that are available and uses all of them (unless the argument n is used).

NOTE: beginCluster may fail when the package 'nws' is installed. You can fix that by removing the 'nws' package, or by setting the cluster type manually, e.g. beginCluster(type="SOCK")

endCluster closes the cluster and removes the object.

The use of the cluster is automatic in these functions: projectRaster, resample and in extract when using polygons.

clusterR is a flexible interface for using cluster with other functions. This function only works with functions that have a Raster* object as first argument and that operate on a cell by cell basis (i.e., there is no effect of neighboring cells) and return an object with the same number of cells as the input raster object. The first argument of the function called must be a Raster* object. There can only be one Raster* object argument. For example, it works with calc and it also works with overlay as long as you provide a single RasterStack or RasterBrick as the first argument.

This function is particularly useful to speed up computations in functions like predict, interpolate, and perhaps calc.

Among other functions, it does _not_ work with merge, crop, mosaic, (dis)aggregate, resample, projectRaster, focal, distance, buffer, direction. But note that projectRaster has a build-in capacity for clustering that is automatically used if beginCluster() has been called.

Usage

```
beginCluster(n, type='SOCK', nice, exclude)
endCluster()
clusterR(x, fun, args=NULL, export=NULL, filename='', cl=NULL, m=2, ...)
```
Arguments

- **n**: Integer. The number of nodes to be used (optional)
- **type**: Character. The cluster type to be used
- **nice**: Integer. To set the priority for the workers, between -20 and 20 (UNIX like platforms only)
- **exclude**: Character. Packages to exclude from loading on the nodes (because they may fail there) but are required/loaded on the master
- **x**: Raster* object
- **fun**: function that takes x as its first argument
- **args**: list with the arguments for the function (excluding x, which should always be the first argument)
- **export**: character. Vector of variable names to export to the cluster nodes such that they are visible to fun (e.g. a parameter that is not passed as an argument)
- **filename**: character. Output filename (optional)
- **cl**: cluster object (do not use it if beginCluster() has been called
- **m**: tuning parameter to determine how many blocks should be used. The number is rounded and multiplied with the number of nodes.
- **...**: additional arguments as for writeRaster

Value

beginCluster and endCluster: None. The side effect is to create or delete a cluster object.
clusterR: as for the function called with argument fun

Note

If you want to write your own cluster-enabled functions see getCluster, returnCluster, and the vignette about writing functions.

Author(s)

Matteo Mattiuzzi and Robert J. Hijmans

Examples

```r
## Not run:
# set up the cluster object for parallel computing
beginCluster()

r <- raster()
r[] <- 1:ncell(r)

x <- clusterR(r, sqrt, verbose=T)

f1 <- function(x) calc(x, sqrt)
```
Get or set the colortable of a RasterLayer. A colortable is a vector of 256 colors in the RGB triple format as returned by the \texttt{rgb} function (e.g. \#C4CDDA).

When setting the colortable, it is assumed that the values are integers in the range [0,255]
Compare-methods

Usage

```r
colortable(x)
colortable(x) <- value
```

Arguments

- `x`: RasterLayer object
- `value`: vector of 256 character values

See Also

- `plotRGB`

Examples

```r
r <- raster(ncol=10, nrow=10)
values(r) <- sample(0:255, ncell(r), replace=TRUE)
ctab <- sample(rainbow(256))
colortable(r) <- ctab
plot(r)
head(colortable(r))
```

Description

These methods compare the location and resolution of Raster* objects. That is, they compare their spatial extent, projection, and number of rows and columns.

For BasicRaster objects you can use `==` and `!=`, the values returned is a single logical value `TRUE` or `FALSE`.

For RasterLayer objects, these operators also compare the values associated with the objects, and the result is a RasterLayer object with logical (Boolean) values.

The following methods have been implemented for RasterLayer objects:

- `==`, `!=`, `>`, `<`, `<=`, `>=`

Value

A logical value or a RasterLayer object, and in some cases the side effect of a new file on disk.
Examples

```r
r1 <- raster()
r1 <- setValues(r1, round(10 * runif(ncell(r1))))
r2 <- setValues(r1, round(10 * runif(ncell(r1))))
as(r1, 'BasicRaster') == as(r2, 'BasicRaster')
r3 <- r1 == r2

b <- extent(0, 360, 0, 180)
r4 <- setExtent(r2, b)
as(r2, 'BasicRaster') != as(r4, 'BasicRaster')
# The following would give an error. You cannot compare RasterLayer
# that do not have the same BasicRaster properties.
# r3 <- r1 > r4
```

---

**compareCRS**

- **Partially compare two CRS objects**

Description

Compare CRS objects

Usage

```r
compareCRS(x, y, unknown=FALSE, verbatim=FALSE, verbose=FALSE)
```

Arguments

- `x` CRS object, or object from which it can be extracted with `projection`, or PROJ.4 format character string
- `y` same as `x`
- `unknown` logical. Return TRUE if x or y is TRUE
- `verbatim` logical. If TRUE compare x and y, verbatim (not partially)
- `verbose` logical. If TRUE, messages about the comparison may be printed

Value

logical

See Also

crs
**compareRaster**

**Compare Raster objects**

**Description**

Evaluate whether a two or more Raster* objects have the same extent, number of rows and columns, projection, resolution, and origin (or a subset of these comparisons).

all.equal is a wrapper around compareRaster with options values=TRUE, stopiffalse=FALSE and showwarning=TRUE.

**Usage**

```r
compareRaster(x, ..., extent=TRUE, rowcol=TRUE, crs=TRUE, res=FALSE, orig=FALSE, rotation=TRUE, values=FALSE, tolerance, stopiffalse=TRUE, showwarning=FALSE)
```

**Arguments**

- **x**
  - Raster* object
- **...**
  - Raster* objects
- **extent**
  - logical. If TRUE, bounding boxes are compared
- **rowcol**
  - logical. If TRUE, number of rows and columns of the objects are compared
- **crs**
  - logical. If TRUE, coordinate reference systems are compared.
- **res**
  - logical. If TRUE, resolutions are compared (redundant when checking extent and rowcol)
- **orig**
  - logical. If TRUE, origins are compared
- **rotation**
  - logical. If TRUE, rotations are compared
- **values**
  - logical. If TRUE, cell values are compared
- **tolerance**
  - numeric between 0 and 0.5. If not supplied, the default value is used (see `rasterOptions`). It sets difference (relative to the cell resolution) that is permissible for objects to be considered 'equal', if they have a non-integer origin or resolution. See `all.equal`.
- **stopiffalse**
  - logical. If TRUE, an error will occur if the objects are not the same
- **showwarning**
  - logical. If TRUE, an warning will be given if objects are not the same. Only relevant when stopiffalse is TRUE

**Examples**

```r
compareCRS("+proj=llcc +lat_1=48 +lat_2=33 +lon_0=-100 +ellps=WGS84","+proj=longlat +datum=WGS84")
compareCRS("+proj=longlat +datum=WGS84 +no_defs +ellps=WGS84 +towgs84=0,0,0","+proj=longlat +datum=WGS84")
compareCRS("+proj=longlat +datum=WGS84 +no_defs +ellps=WGS84 +towgs84=0,0,0","+proj=longlat +datum=WGS84",verbatim=TRUE)
compareCRS("+proj=longlat +datum=WGS84", NA)
compareCRS("+proj=longlat +datum=WGS84", NA, unknown=TRUE)
```
Examples

```r
r1 <- raster()
r2 <- r1
r3 <- r1
cmpareRaster(r1, r2, r3)
nrow(r3) <- 10

# compareRaster(r1, r3)
ncmpareRaster(r1, r3, stopiffalse=FALSE)
ncmpareRaster(r1, r3, rowcol=FALSE)

all.equal(r1, r2)
all.equal(r1, r3)
```

contour | Contour plot

### Description

Contour plot of a RasterLayer.

### Usage

```r
## S4 method for signature 'RasterLayer'
contour(x, maxpixels=100000, ...)
```

### Arguments

- `x` Raster* object
- `maxpixels` maximum number of pixels used to create the contours
- `...` any argument that can be passed to `contour` (graphics package)

### See Also

`persp`, `filledContour`, `rasterToContour`

### Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
plot(r)
contour(r, add=TRUE)
```
**corLocal**

Local correlation coefficient

---

**Description**

Local correlation coefficient for two RasterLayer objects (using a focal neighborhood) or for two RasterStack or Brick objects (with the same number of layers (> 2))

**Usage**

```r
## S4 method for signature 'RasterLayer,RasterLayer'
corLocal(x, y, nb=5,
    method=c("pearson", "kendall", "spearman"), test=FALSE, filename='', ...)

## S4 method for signature 'RasterStack,RasterStack'
corLocal(x, y,
    method=c("pearson", "kendall", "spearman"), test=FALSE, filename='', ...)
```

**Arguments**

- `x` RasterLayer or RasterStack/RasterBrick
- `y` object of the same class as `x`, and with the same number of layers
- `nb` neighborhood size. Either a single integer or a vector of two integers `c(nrow, ncol)`
- `method` character indicating which correlation coefficient is to be used. One of "pearson", "kendall", or "spearman"
- `test` logical. If TRUE, return a p-value
- `filename` character. Output filename (optional)
- `...` additional arguments as for `writeRaster`

**Value**

RasterLayer

**Note**

NA values are omitted

**See Also**

`cor`, `cor.test`
Examples

```r
b <- stack(system.file("external/rlogo.grd", package="raster"))
b <- aggregate(b, 2, mean)

set.seed(0)
b[[2]] <- flip(b[[2]], 'y') + runif(ncell(b))
b[[1]] <- b[[1]] + runif(ncell(b))

x <- corLocal(b[[1]], b[[2]], test=TRUE )
# plot(x)

# only cells where the p-value < 0.1
xm <- mask(x[[1]], x[[2]] < 0.1, maskvalue=FALSE)
plot(xm)

# for global correlation, use the cor function
x <- as.matrix(b)
cor(x, method="spearman")

# use sampleRegular for large datasets
x <- sampleRegular(b, 1000)
cor.test(x[,1], x[,2])

# RasterStack or Brick objects
y <- corLocal(b, flip(b, 'y'))
```

cover

Replace NA values with values of other layers

Description

For Raster* objects: Replace NA values in the first Raster object (x) with the values of the second (y), and so forth for additional Rasters. If x has multiple layers, the subsequent Raster objects should have the same number of layers, or have a single layer only (which will be recycled).

For SpatialPolygons* objects: Areas of x that overlap with y are replaced by (or intersected with) y.

Usage

```r
## S4 method for signature 'RasterLayer,RasterLayer'
cover(x, y, ..., filename='')

## S4 method for signature 'RasterStackBrick,Raster'
cover(x, y, ..., filename='')

## S4 method for signature 'SpatialPolygons,SpatialPolygons'
cover(x, y, ..., identity=FALSE)
```
Crop

**Arguments**

- `x` Raster* or SpatialPolygons* object
- `y` Same as `x`
- `filename` character. Output filename (optional)
- `...` Same as `x`. If `x` is a Raster* object, also additional arguments as for `writeRaster`
- `identity` logical. If TRUE overlapping areas are intersected rather than replaced

**Value**

RasterLayer or RasterBrick object, or SpatialPolygons object

**Examples**

```r
# raster objects
r1 <- raster(ncols=36, nrows=18)
r1[] <- 1:ncell(r1)
r2 <- setValues(r1, runif(ncell(r1)))
r2[r2 < 0.5] <- NA
r3 <- cover(r2, r1)

# SpatialPolygons
if (require(rgdal) & require(rgeos)) {
  p <- shapefile(system.file("external/lux.shp", package="raster"))
  b <- as(extent(6, 6.4, 49.75, 50), 'SpatialPolygons')
  crs(b) <- crs(p)
  b <- SpatialPolygonsDataFrame(b, data.frame(ID_1=9))
  cv1 <- cover(p, b)
  cv2 <- cover(p, b, identity=TRUE)
}
```

**Description**

crop returns a geographic subset of an object as specified by an Extent object (or object from which an extent object can be extracted/created). If `x` is a Raster* object, the Extent is aligned to `x`. Areas included in `y` but outside the extent of `x` are ignored (see `extend` if you want a larger area).

**Usage**

```r
## S4 method for signature 'Raster'
crop(x, y, filename="", snap='near', datatype=NULL, ...)

## S4 method for signature 'Spatial'
crop(x, y, ...)
```
**Arguments**

- **x**
  - Raster* object or SpatialPolygons*, SpatialLines*, or SpatialPoints* object
- **y**
  - Extent object, or any object from which an Extent object can be extracted (see Details)
- **filename**
  - Character, output filename. Optional
- **snap**
  - Character. One of 'near', 'in', or 'out', for use with alignExtent
- **datatype**
  - Character. Output dataType (by default it is the same as the input datatype)
- **...**
  - Additional arguments as for writeRaster

**Details**

Objects from which an Extent can be extracted/created include RasterLayer, RasterStack, RasterBrick and objects of the Spatial* classes from the sp package. You can check this with the extent function. New Extent objects can be also be created with function extent and drawExtent by clicking twice on a plot.

To crop by row and column numbers you can create an extent like this (for Raster x, row 5 to 10, column 7 to 12) `crop(x, extent(x, 5, 10, 7, 15))`

**Value**

RasterLayer or RasterBrick object; or SpatialLines or SpatialPolygons object.

**Note**

values within the extent of a Raster* object can be set to NA with mask

**See Also**

extend, merge

**Examples**

```r
r <- raster(nrow=45, ncol=90)
r[] <- 1:ncell(r)
e <- extent(-160, 10, 30, 60)
rc <- crop(r, e)

# use row and column numbers:
rc2 <- crop(r, extent(r, 5, 10, 7, 15))

# crop Raster* with Spatial* object
b <- as(extent(6, 6.4, 49.75, 50), 'SpatialPolygons')
crs(b) <- crs(r)
rb <- crop(r, b)

# crop a SpatialPolygon* object with another one
if (require(rgdal) & require(rgeos)) {
  p <- shapefile(system.file("external/lux.shp", package="raster"))
  pb <- crop(p, b)
}```
crosstab

}]

| crosstab | Cross-tabulate |

Description

Cross-tabulate two RasterLayer objects, or multiple layers in a RasterStack or RasterBrick to create a contingency table.

Usage

```r
## S4 method for signature 'Raster,Raster'
crosstab(x, y, digits=0, long=FALSE, useNA=FALSE, progress='', ...)

## S4 method for signature 'RasterStack,RasterBrick'
crosstab(x, y, digits=0, long=FALSE, useNA=FALSE, progress='', ...)
```

Arguments

- `x`: Raster* object
- `y`: Raster* object if `x` is a RasterLayer; Can be missing if `x` is a RasterStack or RasterBrick
- `digits`: integer. The number of digits for rounding the values before cross-tabulation
- `long`: logical. If TRUE the results are returned in 'long' format data.frame instead of a table
- `useNA`: logical, indicating if the table should include counts of NA values
- `progress`: character. "text", "window", or "" (the default, no progress bar), only for large files that cannot be processed in one step
- `...`: additional arguments. None implemented

Value

A table or data.frame

See Also

freq, zonal
Examples

```r
r <- raster(nc=5, nr=5)
r[] <- runif(ncell(r)) * 2
s <- setValues(r, runif(ncell(r)) * 3)
crosstab(r, s)

rs <- r/s
r[1:5] <- NA
s[20:25] <- NA
x <- stack(r, s, rs)
crosstab(x, useNA=TRUE, long=TRUE)
```

---

### Description

Cut uses the base function `cut` to classify the values of a Raster* object according to which interval they fall in. The intervals are defined by the argument `breaks`. The leftmost interval corresponds to level one, the next leftmost to level two and so on.

### Usage

```r
cut(x, ...)
```

### Arguments

- `x` A Raster* object
- `...` additional arguments. See cut

### Value

Raster* object

### See Also

subs, reclassify, calc

### Examples

```r
r <- raster(ncols=36, nrows=18)
r[] <- rnorm(ncell(r))
breaks <- -2:2 * 3
rc <- cut(r, breaks=breaks)
```
**cv**

*Coefficient of variation*

**Description**

Compute the coefficient of variation (expressed as a percentage). If there is only a single value, sd is NA and cv returns NA if aszero=FALSE (the default). However, if (aszero=TRUE), cv returns 0.

**Usage**

```r
## S4 method for signature 'ANY'
cv(x, ..., aszero=FALSE, na.rm = FALSE)
## S4 method for signature 'Raster'
cv(x, ..., aszero=FALSE, na.rm = FALSE)
```

**Arguments**

- `x` A vector of numbers (typically integers for modal), or a Raster* object
- `...` additional (vectors of) numbers, or Raster objects
- `aszero` logical. If TRUE, a zero is returned (rather than an NA) if the cv of single value is computed
- `na.rm` Remove (ignore) NA values

**Value**

vector or RasterLayer

**Examples**

```r
data <- c(0,1,2,3,3,3,4,4,4,5,5,6,7,7,8,9,NA)
cv(data, na.rm=TRUE)
```

---

**datasource**

*Are values in memory and/or on disk?*

**Description**

These are helper functions for programmers and for debugging that provide information about whether a Raster object has associated values, and if these are in memory or on disk.

`fromDisk` is TRUE if the data source is a file on disk; and FALSE if the object only exists in memory.

`inMemory` is TRUE if all values are currently in memory (RAM); and FALSE if not (in which case they either are on disk, or there are no values).

`hasValues` is TRUE if the object has cell values.
Usage

fromDisk(x)
inMemory(x)
hasValues(x)

Arguments

x Raster* object

Value

Logical value

Examples

rs <- raster(system.file("external/test.grd", package="raster"))
inMemory(rs)
fromDisk(rs)
rs <- readAll(rs)
inMemory(rs)
fromDisk(rs)
rs <- rs + 1
inMemory(rs)
fromDisk(rs)
rs <- raster(rs)
inMemory(rs)
fromDisk(rs)
rs <- setValues(rs, 1:ncell(rs))
inMemory(rs)
fromDisk(rs)
rs <- writeRaster(rs, filename='test', overwrite=TRUE)
inMemory(rs)
fromDisk(rs)

dataType | Data type
----------|---------------

Description

Get the datatype of a RasterLayer object. The datatype determines the interpretation of values written to disk. Changing the datatype of a Raster* object does not directly affect the way they are stored in memory. For native file formats (.grd/.gri files) it does affect how values are read from file. This is not the case for file formats that are read via rgdal (such as .tif and .img files) or netcdf.

If you change the datatype of a RasterLayer and then read values from a native format file these may be completely wrong, so only do this for debugging or when the information in the header file was wrong. To set the datatype of a new file, you can give a ‘datatype’ argument to the functions that write values to disk (e.g. writeRaster).
**Usage**

dataType(x)
dataType(x) <- value

**Arguments**

x A RasterLayer object
data type (see below)

**Details**

Setting the data type is useful if you want to write values to disk. In other cases use functions such as round()

Datatypes are described by 5 characters. The first three indicate whether the values are integers, decimal number or logical values. The fourth character indicates the number of bytes used to save the values on disk, and the last character indicates whether the numbers are signed (i.e. can be negative and positive values) or not (only zero and positive values allowed)

The following datatypes are available:

<table>
<thead>
<tr>
<th>Datatype definition</th>
<th>minimum possible value</th>
<th>maximum possible value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LG1S</td>
<td>FALSE (0)</td>
<td>TRUE (1)</td>
</tr>
<tr>
<td>INT1S</td>
<td>-127</td>
<td>127</td>
</tr>
<tr>
<td>INT1U</td>
<td>0</td>
<td>255</td>
</tr>
<tr>
<td>INT2S</td>
<td>-32,767</td>
<td>32,767</td>
</tr>
<tr>
<td>INT2U</td>
<td>0</td>
<td>65,534</td>
</tr>
<tr>
<td>INT4S</td>
<td>-2,147,483,647</td>
<td>2,147,483,647</td>
</tr>
<tr>
<td>INT4U</td>
<td>0</td>
<td>4,294,967,296</td>
</tr>
<tr>
<td>FLT4S</td>
<td>-3.4e+38</td>
<td>3.4e+38</td>
</tr>
<tr>
<td>FLT8S</td>
<td>-1.7e+308</td>
<td>1.7e+308</td>
</tr>
</tbody>
</table>

For all integer types, except the single byte types, the lowest (signed) or highest (unsigned) value is used to store NA. Single byte files do not have NA values. Logical values are stored as signed single byte integers, they do have an NA value (-127)

INT4U is available but they are best avoided as R does not support 32-bit unsigned integers.

**Value**

Raster* object

**Examples**

r <- raster(system.file("external/test.grd", package="raster"))
dataType(r)
s <- writeRaster(r, 'new.grd', datatype='INT2U', overwrite=TRUE)
dataType(s)
density

Create density plots of values in a Raster object

Usage

```r
## S4 method for signature 'Raster'
density(x, layer, maxpixels=100000, plot=TRUE, main, ...)
```

Arguments

- `x`: Raster object
- `layer`: numeric. Can be used to subset the layers to plot in a multilayer object (RasterBrick or RasterStack)
- `maxpixels`: the maximum number of (randomly sampled) cells to be used for creating the plot
- `plot`: if TRUE produce a plot, else return a density object
- `main`: main title for each plot (can be missing)
- `...`: Additional arguments passed to `plot`

Value

density plot (and a density object, returned invisibly if `plot=TRUE`)

Examples

```r
logo <- stack(system.file("external/rlogo.grd", package="raster"))
density(logo)
```

dim

Dimensions of a Raster* object

Description

Get or set the number of rows, columns, and layers of a Raster* object. You cannot use this function to set the dimensions of a RasterStack object.

When setting the dimensions, you can provide a row number, or a vector with the row and the column number (for a RasterLayer and a RasterBrick), or a row and column number and the number of layers (only for a RasterBrick)
**direction**

**Usage**

```r
## S4 method for signature 'BasicRaster'
dim(x)
```

**Arguments**

- `x` Raster* object

**Value**

Integer or Raster* object

**See Also**

`ncell`, `extent`, `res`

**Examples**

```r
r <- raster()
dim(r)
dim(r) <- c(18)
dim(r)
dim(r) <- c(18, 36)
dim(r)
b <- brick(r)
dim(b)
dim(b) <- c(10, 10, 5)
dim(b)
```

---

<table>
<thead>
<tr>
<th>direction</th>
<th>Direction</th>
</tr>
</thead>
</table>

**Description**

The direction (azimuth) to or from the nearest cell that is not NA. The direction unit is in radians, unless you use argument `degrees=TRUE`.

**Usage**

```r
## S4 method for signature 'RasterLayer'
direction(x, filename='', degrees=FALSE, from=FALSE, doEdge=FALSE, ...)```
Arguments

- **x**: RasterLayer object
- **filename**: Character. Output filename (optional)
- **degrees**: Logical. If FALSE (the default) the unit of direction is radians.
- **from**: Logical. Default is FALSE. If TRUE, the direction from (instead of to) the nearest cell that is not NA is returned
- **doEdge**: Logical. If TRUE, the boundaries function is called first. This may be efficient in cases where you compute the distance to large blobs. Calling boundaries determines the edge cells that matter for distance computation
- **...**: Additional arguments as for `writeRaster`

Value

RasterLayer

See Also

distance, gridDistance

For the direction between (longitude/latitude) points, see the azimuth function in the geosphere package

Examples

```r
r <- raster(ncol=36,nrow=18)
r[] <- NA
r[306] <- 1
b <- direction(r)
#plot(b)
```

---

**disaggregate**  
**Disaggregate**

Description

Disaggregate a RasterLayer to create a new RasterLayer with a higher resolution (smaller cells). The values in the new RasterLayer are the same as in the larger original cells unless you specify method="bilinear", in which case values are locally interpolated (using the resample function).

Usage

```r
## S4 method for signature 'Raster'
disaggregate(x, fact=NULL, method='', filename='', ...)```

### distance

**Arguments**

- **x**
  - a Raster object
- **fact**
  - integer. amount of disaggregation expressed as number of cells (horizontally and vertically). This can be a single integer or two integers \((x, y)\), in which case the first one is the horizontal disaggregation factor and \(y\) the vertical disaggregation factor. If a single integer value is supplied, cells are disaggregated with the same factor in \(x\) and \(y\) direction.
- **method**
  - Character. '}' or 'bilinear'. If 'bilinear', values are locally interpolated (using the `resample` function)
- **filename**
  - Character. Output filename (optional)
- **...**
  - Additional arguments as for `writeRaster`

**Value**

Raster object

**Author(s)**

Robert J. Hijmans and Jim Regetz

**See Also**

- `aggregate`

**Examples**

```r
r <- raster(ncols=10, nrows=10)
rdat <- disaggregate(r, fact=c(10, 2))
col(rd)
nrow(rd)
r[] <- 1:ncell(r)
rdat <- disaggregate(r, fact=c(4, 2), method='bilinear')
```

---

### Description

For a single `RasterLayer` (\(y\) is missing) this method computes the distance, for all cells that are `NA`, to the nearest cell that is not `NA`. The distance unit is in meters if the `RasterLayer` is not projected (`+proj=longlat`) and in map units (typically also meters) when it is projected.

If two `RasterLayer` objects are provided, the cell-value distances are computed. If two Spatial vector type objects are provided, the distances between pairs of geographic object are computed.
Usage

```
## S4 method for signature 'RasterLayer,missing'
distance(x, y, filename='', doEdge=TRUE, ...)
## S4 method for signature 'RasterLayer,RasterLayer'
distance(x, y, ...)
## S4 method for signature 'Spatial,Spatial'
distance(x, y, ...)
```

Arguments

- `x` RasterLayer object
- `y` missing, RasterLayer or Spatial object
- `filename` Character. Filename for the output RasterLayer (optional)
- `doEdge` Logical. If TRUE, the `boundaries` function is called first. This may be efficient in cases where you compute the distance to large blobs. Calling `boundaries` determines the edge cells that matter for distance computation
- `...` Additional arguments as for `writeRaster`

Value

RasterLayer

See Also

`distanceFromPoints`, `gridDistance`, `pointDistance`

See the `gdistance` package for more advanced distances, and the `geosphere` package for great-circle distances (and more) between points in longitude/latitude coordinates.

Examples

```
r <- raster(ncol=36,nrow=18)
r[] <- NA
r[500] <- 1
dist <- distance(r)
plot(dist / 1000)
```

---

**distanceFromPoints**

**Distance from points**

Description

The function calculates the distance from a set of points to all cells of a RasterLayer. The distance unit is in meters if the RasterLayer is not projected (+proj=longlat) and in map units (typically meters) when it is projected.
draw

Usage

distanceFromPoints(object, xy, filename='', ...)

Arguments

object Raster object
xy matrix of x and y coordinates, or a SpatialPoints* object.
filename character. Optional filename for the output RasterLayer
... Additional arguments as for writeRaster

Value

RasterLayer object

See Also

distance, gridDistance, pointDistance

Examples

r <- raster(ncol=36, nrow=18)
xy = c(0,0)
dist <- distanceFromPoints(r, xy)
#plot(dist)

---

draw Draw a line or polygon

Description

Draw a line or polygon on a plot (map) and save it for later use. After calling the function, start clicking on the map. To finish, right-click and select 'stop'.

Usage

drawPoly(sp=TRUE, col='red', lwd=2, ...)
drawLine(sp=TRUE, col='red', lwd=2, ...)

Arguments

sp logical. If TRUE, the output will be a sp object (SpatialPolygons or SpatialLines). Otherwise a matrix of coordinates is returned
col the color of the lines to be drawn
lwd the width of the lines to be drawn
... additional arguments padded to locator
Value

If sp=TRUE a SpatialPolygons or SpatialLines object; otherwise a matrix of coordinates

See Also

locator

drawExtent

Create an Extent object by drawing on a map

Description

Click on two points of a plot (map) to obtain an object of class Extent ('bounding box')

Usage

drawExtent(show=TRUE, col="red")

Arguments

show
logical. If TRUE, the extent will be drawn on the map

col
sets the color of the lines of the extent

Value

Extent

Examples

## Not run:

r1 <- raster(nrow=10, ncol=10)
r1[] <- runif(ncell(r1))
plot(r1)
# after running the following line, click on the map twice
e <- drawExtent()
# after running the following line, click on the map twice
mean(values(crop(r1, drawExtent())))

## End(Not run)
erase

Erase parts of a Spatial* object

Description

Erase parts of a Spatial* objects with another Spatial* object

Usage

```r
## S4 method for signature 'SpatialPolygons,SpatialPolygons'
erase(x, y, ...)
```

Arguments

- `x`: Spatial* object
- `y`: Spatial* object
- `...`: Additional arguments (none)

Value

Spatial*

Author(s)

Robert J. Hijmans

Examples

```r
if (require(rgdal) & require(rgeos)) {
  p <- shapefile(system.file("external/lux.shp", package="raster"))
  b <- as(extent(6, 6.4, 49.75, 50), 'SpatialPolygons')
  projection(b) <- projection(p)
  e <- erase(p, b)
  plot(e)
}
```

extend

Extend

Description

Extend returns an Raster* object with a larger spatial extent. The output Raster object has the outer minimum and maximum coordinates of the input Raster and Extent arguments. Thus, all of the cells of the original raster are included. See `crop` if you (also) want to remove rows or columns.

There is also an extend method for Extent objects to enlarge (or reduce) an Extent. You can also use algebraic notation to do that (see examples).

This function has replaced function "expand" (to avoid a name conflict with the Matrix package).
Usage

```r
## S4 method for signature 'Raster'
extend(x, y, value=NA, filename='', ...)  
## S4 method for signature 'Extent'
extend(x, y, ...)  
```

Arguments

- `x`: Raster or Extent object
- `y`: If `x` is a Raster object, `y` should be an Extent object, or any object that is or has an Extent object, or an object from which it can be extracted (such as sp objects). Alternatively, you can provide a numeric vector of length 2 indicating the number of rows and columns that need to be added (or a single number when the number of rows and columns is equal). If `x` is an Extent object, `y` should be a numeric vector of 1, 2, or 4 elements
- `value`: value to assign to new cells
- `filename`: Character (optional)
- `...`: Additional arguments as for `writeRaster`

Value

A `RasterLayer` or `RasterBrick`, or `Extent`

Author(s)

Robert J. Hijmans and Etienne B. Racine (Extent method)

See Also

`crop`, `merge`

Examples

```r
r <- raster(xmn=-150, xmx=-120, ymx=60, ymn=30, ncol=36, nrow=18)
r[] <- 1:ncell(r)
e <- extent(-180, 0, 0, 90)
re <- extend(r, e)

# extend with a number of rows and columns (at each side)
re2 <- extend(r, c(2,10))

# Extent object
e <- extent(r)
e
extend(e, 10)
extend(e, 10, -10, 0, 20)
e + 10
e * 2
```
extension

Filename extensions

Description
Get or change a filename extension

Usage
extension(filename, value=NULL, maxchar=10)
extension(filename) <- value

Arguments
filename A filename, with or without the path
value A file extension with or without a dot, e.g., ".txt" or "txt"
maxchar Maximum number of characters after the last dot in the filename, for that string to be considered a filename extension

Value
A file extension, filename or path.
If ext(filename) is used without a value argument, it returns the file extension; otherwise it returns the filename (with new extensions set to value

Examples
fn <- "c:/temp folder/filename.extension"
extension(fn)
extension(fn) <- ".txt"
extension(fn)
fn <- extension(fn, ".document")
extension(fn)
extension(fn, maxchar=4)

extent
Extent

Description
This function returns an Extent object of a Raster* or Spatial* object (or an Extent object), or creates an Extent object from a 2x2 matrix (first row: xmin, xmax; second row: ymin, ymax), vector (length=4; order= xmin, xmax, ymin, ymax) or list (with at least two elements, with names 'x' and 'y')
bbox returns a sp package like 'bbox' object (a matrix)
Extent math

Usage

extent(x, ...)

Arguments

x Raster* or Extent object, a matrix, or a vector of four numbers
... Additional arguments. When x is a single number representing 'xmin', you can pass three additional numbers (xmax, ymin, ymax)
When x is a Raster* object, you can pass four additional arguments to crop the extent: r1, r2, c1, c2, representing the first and last row and column number

Value

Extent object

Author(s)

Robert J. Hijmans; Etienne Racine wrote the extent function for a list

See Also

extent, drawExtent

Examples

r <- raster()
extent(r)
extent(c(0, 20, 0, 20)) # is equivalent to
extent(0, 20, 0, 20)
extent(matrix(c(0, 0, 20, 20), nrow=2))
x <- list(x=c(0,1,2), y=c(-3,5))
extent(x)

# crop the extent by row and column numbers
extent(r, 1, 20, 10, 30)

Description

use round(x, digits=0) to round the coordinates of an Extent object to the number of digits specified. This can be useful when dealing with a small imprecision in the data (e.g. 179.9999 instead of 180). floor and ceiling move the coordiantes to the outer or inner whole integer numbers.

It is also possible to use Arithmetic functions with Extent objects (but these work perhaps unexpectedly!)

See Math-methods for these (and many more) methods with Raster* objects.
Usage

## S4 method for signature 'Extent'
floor(x)
## S4 method for signature 'Extent'
ceiling(x)

Arguments

x  Extent object

See Also

Math-methods

Examples

e <- extent(c(0.999999, 10.000001, -60.4, 60))
round(e)
ceiling(e)
floor(e)

Description

Objects of class Extent are used to define the spatial extent (extremes) of objects of the BasicRaster and Raster* classes.

Objects from the Class

You can use the `extent` function to create Extent objects, or to extract them from Raster* and Spatial* objects.

Slots

- `xmin`: minimum x coordinate
- `xmax`: maximum x coordinate
- `ymin`: minimum y coordinate
- `ymax`: maximum y coordinate

Methods

- `show` display values of a Extent object

See Also

- `extent`, `setExtent`
Examples

```r
ext <- extent(-180, 180, -90, 90)

extract(ext)
```

---

**Description**

Extract values from a Raster* object at the locations of other spatial data. You can use coordinates (points), lines, polygons or an Extent (rectangle) object. You can also use cell numbers to extract values.

If \( y \) represents points, `extract` returns the values of a Raster* object for the cells in which a set of points fall. If \( y \) represents lines, the `extract` method returns the values of the cells of a Raster* object that are touched by a line. If \( y \) represents polygons, the `extract` method returns the values of the cells of a Raster* object that are covered by a polygon. A cell is covered if its center is inside the polygon (but see the `weights` option for considering partly covered cells; and argument `small` for getting values for small polygons anyway).

It is also possible to extract values for point locations from SpatialPolygons.

**Usage**

```r
## S4 method for signature 'Raster, matrix'
extract(x, y, method='simple', buffer=NULL, small=FALSE, cellnumbers=FALSE,
fun=NULL, na.rm=TRUE, layer, nl, df=FALSE, factors=FALSE, ...)

## S4 method for signature 'Raster, SpatialLines'
extract(x, y, fun=NULL, na.rm=FALSE, cellnumbers=FALSE, df=FALSE, layer,
nl, factors=FALSE, along=FALSE, sp=FALSE, ...)

## S4 method for signature 'Raster, SpatialPolygons'
extract(x, y, fun=NULL, na.rm=FALSE, weights=FALSE,
normalizeWeights=TRUE, cellnumbers=FALSE, small=TRUE, df=FALSE, layer, nl,
factors=FALSE, sp=FALSE, ...)

## S4 method for signature 'SpatialPolygons, SpatialPoints'
extract(x, y, ...)
```

**Arguments**

- \( x \) : Raster* object
- \( y \) : points represented by a two-column matrix or data.frame, or \texttt{SpatialPoints*}; \texttt{SpatialPolygons*}; \texttt{SpatialLines}; \texttt{Extent}; or a numeric vector representing cell numbers
extract

method character. 'simple' or 'bilinear'. If 'simple' values for the cell a point falls in are returned. If 'bilinear' the returned values are interpolated from the values of the four nearest raster cells.

buffer numeric. The radius of a buffer around each point from which to extract cell values. If the distance between the sampling point and the center of a cell is less than or equal to the buffer, the cell is included. The buffer can be specified as a single value, or as a vector of the length of the number of points. If the data are not projected (latitude/longitude), the unit should be meters. Otherwise it should be in map-units (typically also meters).

small logical. If TRUE and y represents points and a buffer argument is used, the function always return a number, also when the buffer does not include the center of a single cell. The value of the cell in which the point falls is returned if no cell center is within the buffer. If y represents polygons, a value is also returned for relatively small polygons (e.g. those smaller than a single cell of the Raster* object), or polygons with an odd shape, for which otherwise no values are returned because they do not cover any raster cell centers. In some cases, you could alternatively use the centroids of such polygons, for example using extract(x, coordinates(y)) or extract(x, coordinates(y), method='bilinear').

fun function to summarize the values (e.g. mean). The function should take a single numeric vector as argument and return a single value (e.g. mean, min or max), and accept a na.rm argument. Thus, standard R functions not including an na.rm argument must be wrapped as in this example: fun=function(x,...)length(x). If y represents points, fun is only used when a buffer is used (and hence multiple values per spatial feature would otherwise be returned).

na.rm logical. Only useful when an argument fun is supplied. If na.rm=TRUE (the default value), NA values are removed before fun is applied. This argument may be ignored if the function used has a ... argument and ignores an additional na.rm argument

cellnumbers logical. If cellnumbers=TRUE, cell-numbers will also be returned (if no fun argument is supplied, and when extracting values with points, if buffer is NULL)

df logical. If df=TRUE, results will be returned as a data.frame. The first column is a sequential ID, the other column(s) are the extracted values

weights logical. If TRUE and normalizeWeights=FALSE, the function returns, for each polygon, a matrix with the cell values and the approximate fraction of each cell that is covered by the polygon(rounded to 1/100). If TRUE and normalizeWeights=TRUE the weights are normalized such that they add up to one. The weights can be used for averaging; see examples. This option can be useful (but slow) if the polygons are small relative to the cells size of the Raster* object

normalizeWeights logical. If TRUE, weights are normalized such that they add up to one for each polygon

factors logical. If TRUE, factor values are returned, else their integer representation is returned

layer integer. First layer for which you want values (if x is a multilayer object)

nl integer. Number of layers for which you want values (if x is a multilayer object)
boolean. Should returned values be ordered to go along the lines?
sp

boolean. Should the extracted values be added to the data.frame of the Spatial* object y? This only applies if y is a Spatial* object and, for SpatialLines and SpatialPolygons, if fun is not NULL. In this case the returned value is the expanded Spatial object

... additional arguments (none implemented)

Value
A vector for RasterLayer objects, and a matrix for RasterStack or RasterBrick objects. A list (or a data.frame if df=TRUE) if y is a SpatialPolygons* or SpatialLines* object or if a buffer argument is used (but not a fun argument). If sp=TRUE and y is a Spatial* object and fun is not NULL a Spatial* object is returned. The order of the returned values corresponds to the order of object y. If df=TRUE, this is also indicated in the first variable ("ID").

# extract values with an extent
e <- extent(150, 170, -60, -40)
extract(r, e)
#plot(r)
#plot(e, add=T)
Description

These are shorthand methods that call other methods that should normally be used, such as `getValues`, `extract`, `crop`.

`object[i]` can be used to access values of a Raster* object, using cell numbers. You can also use row and column numbers as index, using `object[i,j]` or `object[i,]` or `object[,,j]`. In addition you can supply an Extent, SpatialPolygons, SpatialLines or SpatialPoints object.

If `drop=TRUE` (the default) cell values are returned (a vector for a RasterLayer, a matrix for a RasterStack or RasterBrick). If `drop=FALSE` a Raster* object is returned that has the extent covering the requested cells, and with all other non-requested cells within this extent set to `NA`.

If you supply a RasterLayer, its values will be used as logical (TRUE/FALSE) indices if both Raster objects have the same extent and resolution; otherwise the cell values within the extent of the RasterLayer are returned.

Double brackes `[[ ]]` can be used to extract one or more layers from a multi-layer object.

Methods

`x[i]`
`x[i,j]`

Arguments

`x` a Raster* object
`i` cell number(s), row number(s), a (logical) RasterLayer, Spatial* object
`j` column number(s) (only available if `i` is (are) a row number(s))
`drop` If `TRUE`, cell values are returned. Otherwise, a Raster* object is returned

See Also

`getValues`, `setValues`, `extract`, `crop`, `rasterize`

Examples

```r
r <- raster(ncol=10, nrow=5)
r[] <- 1:nCell(r)

r[1]
r[1:10]
r[1,]
r[,,1]
r[1:2, 1:2]

s <- stack(r, sqrt(r))
s[1:3]
s[[2]]
```
Extreme coordinates

**Description**
These functions return or set the extreme coordinates of a Raster* object; and return them for Spatial* objects.

**Usage**

- `xmin(x)`
- `xmax(x)`
- `ymin(x)`
- `ymax(x)`

```r
xmin(x) <- value
xmax(x) <- value
ymin(x) <- value
ymax(x) <- value
```

**Arguments**
- `x` A Raster* object
- `value` A new x or y coordinate

**Value**
a single number

**See Also**
- `extent`, `dimensions`

**Examples**

```r
r <- raster(xmn=-0.5, xmx = 9.5, ncols=10)
xmin(r)
xmax(r)
ymin(r)
ymax(r)
xmin(r) <- -180
xmax(r) <- 180
```
extremeValues

Minimum and maximum values

Description

Returns the minimum or maximum value of a RasterLayer or layer in a RasterStack

Usage

minValue(x, ...)
maxValue(x, ...)

Arguments

x

RasterLayer or RasterStack object

...  

Additional argument: layer number (for RasterStack or RasterBrick objects)

Details

If a Raster* object is created from a file on disk, the min and max values are often not known (depending on the file format). You can use setMinMax to set them in the Raster* object.

Value

a number

Examples

r <- raster()
r <- setValues(r, 1:ncell(r))
minValue(r)
maxValue(r)
r <- setValues(r, round(100 * runif(ncell(r)) + 0.5))
minValue(r)
maxValue(r)
r <- raster(system.file("external/test.grd", package="raster"))
minValue(r)
maxValue(r)
Factors

Description

These functions allow for defining a RasterLayer as a categorical variable. Such a RasterLayer is linked to other values via a "Raster Attribute Table" (RAT). Thus the cell values are an index, whereas the actual values of interest are in the RAT. The RAT is a data.frame. The first column in the RAT ("ID") has the unique cell values of the layer; this column should normally not be changed. The other columns can be of any basic type (factor, character, integer, numeric or logical). The functions documented here are mainly available such that files with a RAT can be read and processed; currently there is not too much further support. Whether a layer is defined as a factor or not is currently ignored by almost all functions. An exception is the 'extract' function (when used with option df=TRUE).

Function 'levels' returns the RAT for inspection. It can be modified and set using `levels <- value` (but use caution as it is easy to mess things up).

as.factor and ratify create a layer with a RAT table. Function 'deratify' creates a single layer for a (or each) variable in the RAT table.

Usage

```r
is.factor(x)
as.factor(x)
levels(x)
```

```r
factorValues(x, v, layer=1, att=NULL, append.names=FALSE)
```

```r
ratify(x, filename='', count=FALSE, ...)
deratify(x, att=NULL, layer=1, complete=FALSE, drop=TRUE, fun='mean', filename='', ...)
asFactor(x, ...)
```

Arguments

- `x` Raster* object
- `v` integer cell values
- `layer` integer > 0 indicating which layer to use (in a RasterStack or RasterBrick)
- `att` numeric or character. Which variable(s) in the RAT table should be used. If NULL, all variables are extracted. If using a numeric, skip the first two default columns
- `append.names` logical. Should names of data.frame returned by a combination of the name of the layer and the RAT variables? (can be useful for multilayer objects)
- `filename` character. Optional
- `count` logical. If TRUE, a columns with frequencies is added
... additional arguments as for `writeRaster`

**complete** logical. If TRUE, the layer returned is no longer a factor

**drop** logical. If TRUE a factor is converted to a numerical value if possible

**fun** character. Used to get a single value for each class for a weighted RAT table. 'mean', 'min', 'max', 'smallest', or 'largest'

**Value**

Raster* object; list (levels); boolean (is.factor); matrix (factorValues)

**Note**

asFactor is deprecated and should not be used

**Examples**

```r
set.seed(0)
r <- raster(nrow=10, ncol=10)
r[] <- runif(ncell(r)) * 10
is.factor(r)

r <- round(r)
f <- as.factor(r)
is.factor(f)

x <- levels(f)[[1]]
x
x$code <- letters[10:20]
levels(f) <- x
levels(f)
f

r <- raster(nrow=10, ncol=10)
r[] = 1
r[51:100] = 2
r[3:6, 1:5] = 3
r <- ratify(r)

rat <- levels(r)[[1]]
rat$landcover <- c('Pine', 'Oak', 'Meadow')
rat$code <- c(12,25,30)
levels(r) <- rat
r

# extract values for some cells
i <- extract(r, c(1,2, 25,100))
i
# get the attribute values for these cells
factorValues(r, i)

# write to file:
```
```r
rr <- writeRaster(r, 'test.grd', overwrite=TRUE)
rr

# create a single-layer factor
x <- deratify(r, 'landcover')
x
is.factor(x)
levels(x)
```

<table>
<thead>
<tr>
<th>filename</th>
<th>Filename</th>
</tr>
</thead>
</table>

### Description
Get the filename of a Raster* object. You cannot set the filename of an object (except for RasterStack objects); but you can provide a 'filename=' argument to a function that creates a new RasterLayer or RasterBrick* object.

### Usage
`filename(x)`

### Arguments
- `x` A Raster* object

### Value
a Raster* object

### Examples
```r
r <- raster(system.file("external/test.grd", package="raster") )
filename(r)
```

<table>
<thead>
<tr>
<th>filledContour</th>
<th>Filled contour plot</th>
</tr>
</thead>
</table>

### Description
Filled contour plot of a RasterLayer. This is a wrapper around `filled.contour` for RasterLayer objects.

### Usage
`filledContour(x, y=1, maxpixels=100000, ...)`
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>A Raster* object</td>
</tr>
<tr>
<td>y</td>
<td>Integer. The layer number of x (if x has multiple layers)</td>
</tr>
<tr>
<td>maxpixels</td>
<td>The maximum number of pixels</td>
</tr>
<tr>
<td>...</td>
<td>Any argument that can be passed to <code>filled.contour</code> (graphics package)</td>
</tr>
</tbody>
</table>

See Also

`filled.contour`, `persp`, `plot`

Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
filledContour(r)
```

Description

Flip the values of a Raster* object by inverting the order of the rows (direction='y') or the columns (direction='x').

Usage

`flip(x, direction, ...)`

Arguments

- `x`: Raster* object
- `direction`: Character. 'y' or 'x'; or 1 (=x) or 2 (=y)
- `...`: Additional arguments as for `writeRaster`

Value

RasterLayer or RasterBrick

See Also

transpose: `t`, `rotate`

Examples

```r
r <- raster(nrow=18, ncol=36)
m <- matrix(1:ncell(r), nrow=18)
r[] <- as.vector(t(m))
rx <- flip(r, direction='x')
r[] <- as.vector(m)
ry <- flip(r, direction='y')
```
Description

Compute the flow path (drainage path) starting at a given point. See package gdistance for more path computations.

Usage

flowPath(x, p, ...)

Arguments

x  RasterLayer of flow direction (as can be created with terrain)
p  starting point. Either two numbers: x (longitude) and y (latitude) coordinates; or a single cell number
...  additional arguments (none implemented)

Value

numeric (cell numbers)

Author(s)

Ashton Shortridge

Examples

data(volcano)
v <- raster(volcano, xmn=2667400, xmx=2668010, ymn=6478700, ymx=6479570, crs=“+init=epsg:27200”)
fd <- terrain(v, opt = “flowdir”)

path <- flowPath(fd, 2407)
xy <- xyFromCell(fd, path)
plot(v)
lines(xy)
Description

Calculate focal ("moving window") values for the neighborhood of focal cells using a matrix of weights, perhaps in combination with a function.

Usage

```r
## S4 method for signature 'RasterLayer'
focal(x, w, fun=NULL, filename='', na.rm=FALSE, pad=FALSE, padValue=NA, NAonly=FALSE, ...)
```

Arguments

- `x`: RasterLayer
- `w`: matrix of weights (the moving window), e.g. a 3 by 3 matrix with values 1; see Details. The matrix does not need to be square, but the sides must be odd numbers. If you need even sides, you can add a column or row with weights of zero
- `fun`: function (optional). The function fun should take multiple numbers, and return a single number. For example mean, modal, min or max. It should also accept a `na.rm` argument (or ignore it, e.g. as one of the 'dots' arguments. For example, the length will fail, but `function(x, ...)(na.omit(length(x)))` works.
- `filename`: character. Filename for a new raster (optional)
- `na.rm`: logical. If TRUE, NA will be removed from focal computations. The result will only be NA if all focal cells are NA. Except for some special cases (weights of 1, functions like min, max, mean), using `na.rm=TRUE` is generally not a good idea in this function because it will unbalance the effect of the weights
- `pad`: logical. If TRUE, additional 'virtual' rows and columns are padded to x such that there are no edge effects. This can be useful when a function needs to have access to the central cell of the filter
- `padValue`: numeric. The value of the cells of the padded rows and columns
- `NAonly`: logical. If TRUE, only cell values that are NA are replaced with the computed focal values
- `...`: Additional arguments as for `writeRaster`

Details

focal uses a matrix of weights for the neighborhood of the focal cells. The default function is `sum`. It is computationally much more efficient to adjust the weights-matrix than to use another function through the `fun` argument. Thus while the following two statements are equivalent (if there are no NA values), the first one is faster than the second one:

```r
a <- focal(x, w=matrix(1/9, nc=3, nr=3))
```
There is, however, a difference if NA values are considered. One can use the na.rm=TRUE option which may make sense when using a function like mean. However, the results would be wrong when using a weights matrix.

Laplacian filter: \( \text{filter}=\text{matrix}(c(0,1,0,1,-4,1,0,1), \text{nrow}=3) \)

Sobel filter: \( \text{filter}=\text{matrix}(c(1,2,1,0,0,-1,-2,-1) / 4, \text{nrow}=3) \)

see the \texttt{focalWeight} function to create distance based circular, rectangular, or Gaussian filters.

**Value**

RasterLayer

**See Also**

\texttt{focalWeight}

**Examples**

```r
r <- raster(ncols=36, nrows=18, xmn=0)
r[] <- runif(ncell(r))

# 3x3 mean filter
r3 <- focal(r, w=matrix(1/9, nrow=3, ncol=3))

# 5x5 mean filter
r5 <- focal(r, w=matrix(1/25, nrow=5, ncol=5))

# Gaussian filter
gf <- focalWeight(r, 2, "Gauss")
gr <- focal(r, w=gf)

# The max value for the lower-rigth corner of a 3x3 matrix around a focal cell
f = matrix(c(0,0,0,0,1,1,0,1,1), nrow=3)
f
rm <- focal(r, w=f, fun=max)

# global lon/lat data: no 'edge effect' for the columns
xmin(r) <- -180
r3g <- focal(r, w=matrix(1/9, nrow=3, ncol=3))
```

```r
## Not run:
## focal can be used to create a cellular automaton

# Conway's Game of Life
w <- matrix(c(1,1,1,1,0,1,1,1,1), nr=3, nc=3)
gameOfLife <- function(x) {
  f <- focal(x, w=w, pad=TRUE, padValue=0)
  # cells with less than two or more than three live neighbours die
  x[f<2 | f>3] <- 0
  # cells with three live neighbours become alive
  return(x)
}
```

b <- focal(x, w=matrix(1,3,3), fun=mean)
focalWeight

# simulation function
sim <- function(x, fun, n=100, pause=0.25) {
  for (i in 1:n) {
    x <- fun(x)
    plot(x, legend=FALSE, asp=NA, main=i)
    dev.flush()
    Sys.sleep(pause)
  }
  invisible(x)
}

# Gosper glider gun
m <- matrix(0, nc=48, nr=34)
m[c(40, 41, 74, 75, 380, 381, 382, 413, 417, 446, 452, 480, 486, 517, 549, 553, 584, 585, 586, 619, 718, 719, 720, 752, 753, 754, 785, 789, 852, 853, 857, 858, 1194, 1195, 1228, 1229)] <- 1
init <- raster(m)

# run the model
sim(init, gameOfLife, n=150, pause=0.05)

## End(Not run)

---

**focalWeight**

*Focal weights matrix*

**Description**

Calculate focal ("moving window") weight matrix for use in the `focal` function. The sum of the values adds up to one.

**Usage**

`focalWeight(x, d, type=c('circle', 'Gauss', 'rectangle'))`

**Arguments**

- `x` Raster* object
- `d` numeric. If `type=ci`rcle, the radius of the circle (in units of the CRS). If `type=rectangle` the dimension of the rectangle (one or two numbers). If `type=Gauss` the size of sigma, and optionally another number to determine the size of the matrix returned (default is 3 times sigma)
- `type` character indicating the type of filter to be returned
Value

matrix that can be used in \texttt{focal}

Examples

```r
r <- raster(ncols=36, nrows=18, xmn=0)
# Gaussian filter for square cells
gf <- focalWeight(r, 2, "Gauss")
```

---

**Description**

Frequency table of the values of a RasterLayer.

**Usage**

```r
## S4 method for signature 'RasterLayer'
freq(x, digits=0, value=NULL, useNA='ifany', progress='', ...)  
## S4 method for signature 'RasterStackBrick'
freq(x, digits=0, value=NULL, useNA='ifany', merge=FALSE, progress='', ...)  
```

**Arguments**

- \texttt{x} \hspace{1cm} \texttt{RasterLayer}
- \texttt{digits} \hspace{1cm} non-negative integer for rounding the cell values. Argument is passed to \texttt{round}
- \texttt{value} \hspace{1cm} numeric, logical or \texttt{NA}. An optional single value to only count the number of cells with that value
- \texttt{useNA} \hspace{1cm} character. What to do with \texttt{NA} values? Options are "no", "ifany", "always". See to \texttt{table}
- \texttt{progress} \hspace{1cm} character to specify a progress bar. Choose from 'text', 'window', or " (the default, no progress bar)
- \texttt{merge} \hspace{1cm} logical. If \texttt{TRUE} the list will be merged into a single data.frame
- ... \hspace{1cm} additional arguments (none implemented)

**Value**

matrix (\texttt{RasterLayer}). List of matrices (one for each layer) or \texttt{data.frame} (if \texttt{merge=TRUE}) (RasterStack or RasterBrick)

**See Also**

\texttt{crosstab} and \texttt{zonal}
Gain and offset

Examples

```r
r <- raster(nrow=18, ncol=36)
r[] <- runif(ncell(r))
r[1:5] <- NA
r <- r * r * r * 5
freq(r)

freq(r, value=2)

s <- stack(r, r*2, r*3)
freq(s, merge=TRUE)
```

Description

These functions can be used to get or set the gain and offset parameters used to transform values when reading them from a file. The gain and offset parameters are applied to the raw values using the formula below:

\[
\text{value} \leftarrow \text{value} \times \text{gain} + \text{offset}
\]

The default value for gain is 1 and for offset is 0. 'gain' is sometimes referred to as 'scale'.

Note that setting gain and/or offset are intended to be used with values that are stored in a file. For a Raster* object with values in memory, assigning gain or offset values will lead to the immediate computation of new values; in such cases it would be clearer to use Arith-methods.

Usage

```
 gain(x)
 gain(x) <- value
 offs(x)
 offs(x) <- value
```

Arguments

- `x` : Raster* object
- `value` : Single numeric value

Value

- Raster* object or numeric value(s)
Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
gain(r)
offs(r)
r[1505:1510]
gain(r) <- 10
offs(r) <- 5
r[1505:1510]
```

---

**geom**  
*Get the coordinates of a vector type* Spatial* object*

---

**Description**

Extract the coordinates of a Spatial object

**Usage**

```r
## S4 method for signature 'SpatialPolygons'
geom(x, sepNA=FALSE, ...)
```

**Arguments**

- `x`  
  SpatialPolygons*, SpatialLines*, or SpatialPoints* object
- `sepNA`  
  logical. If TRUE, geometries are separated by a row with NA values
- `...`  
  additional arguments, none implemented

**Value**

Matrix with 6, (5 SpatialLines), or 3 (SpatialPoints) columns. object (sequential object number) part (sequential part number within the object; not for SpatialPoints), cump (cumulative part number; not for SpatialPoints), hole (is this a hole or not; only for SpatialPolygons), x (x coordinate or longitude), y (y coordinate or latitude)

**See Also**

coordinates, geometry

**Examples**

```r
if (require(rgdal) & require(rgeos)) {
p <- shapefile(system.file("external/lux.shp", package="raster"))
x <- geom(p)
}
```
**getGeo**

*Get geographic data*

**Description**

Get geographic data for anywhere in the world. Data are read from files that are first downloaded if necessary. Function `ccodes` returns country names and the ISO codes.

**Usage**

```r
getData(name, download=TRUE, path='', ...) ccodes()
```

**Arguments**

- **name**
  - Data set name, currently supported are 'GADM', 'countries', 'SRTM', 'alt', and 'worldclim'. See Details for more info.
- **download**
  - Logical. If TRUE data will be downloaded if not locally available.
- **path**
  - Character. Path name indicating where to store the data. Default is the current working directory.
- **...**
  - Additional required (!) parameters. These are data set specific. See Details.

**Details**

'alt' stands for altitude (elevation); the data were aggregated from SRTM 90 m resolution data between -60 and 60 latitude. 'GADM' is a database of global administrative boundaries. 'worldclim' is a database of global interpolated climate data. 'SRTM' refers to the hole-filled CGIAR-SRTM (90 m resolution). 'countries' has polygons for all countries at a higher resolution than the 'wrld_simpl' data in the maptools package.

If `name` is 'alt' or 'GADM' you must provide a 'country=' argument. Countries are specified by their 3 letter ISO codes. Use `getData('ISO3')` to see these codes. In the case of GADM you must also provide the level of administrative subdivision (0=country, 1=first level subdivision). In the case of alt you can set 'mask' to FALSE. If it is TRUE values for neighbouring countries are set to NA. For example:

```r
getData('GADM', country='FRA', level=1)
getData('alt', country='FRA', mask=TRUE)
```

If `name` is 'SRTM' you must provide 'lon' and 'lat' arguments (longitude and latitude). These should be single numbers somewhere within the SRTM tile that you want.

```r
getData('SRTM', lon=5, lat=45)
```

If `name`='worldclim' you must also provide arguments `var` and a resolution `res`. Valid variables names are 'tmin', 'tmax', 'prec' and 'bio'. Valid resolutions are 0.5, 2.5, 5, and 10 (minutes of a degree). In the case of `res=0.5`, you must also provide a `lon` and `lat` argument for a tile; for the lower resolutions global data will be downloaded. In all cases there are 12 (monthly) files for each variable except for 'bio' which contains 19 files.
To get (projected) future climate data (CMIP5), you must provide arguments \texttt{var} and \texttt{res} as above. Only resolutions 2.5, 5, and 10 are currently available. In addition, you need to provide \texttt{model}, \texttt{rcp} and \texttt{year}. For example,

```r
getData('CMIP5', var='tmin', res=10, rcp=85, model='AC', year=70)
```

The function \texttt{getValues} returns all values or the values for a number of rows of a \texttt{Raster*} object. Values returned for a \texttt{RasterLayer} are a vector. The values returned for a \texttt{RasterStack} or \texttt{RasterBrick} are always a matrix, with the rows representing cells, and the columns representing layers.

\texttt{getValues} is a shorthand version of \texttt{getValues} (for all rows).

\section*{getValues}

\textit{Get raster cell values}

\section*{Description}

\texttt{getValues} returns all values or the values for a number of rows of a \texttt{Raster*} object. Values returned for a \texttt{RasterLayer} are a vector. The values returned for a \texttt{RasterStack} or \texttt{RasterBrick} are always a matrix, with the rows representing cells, and the columns representing layers.

\texttt{values} is a shorthand version of \texttt{getValues} (for all rows).

\section*{Usage}

```r
getValues(x, row, nrows, ...)
values(x, ...)
```
Arguments

- **x**: Raster* object
- **row**: Numeric. Row number, should be between 1 and nrow(x), or missing in which case all values are returned
- **nrows**: Numeric. Number of rows. Should be an integer > 0, or missing
- **...**: Additional arguments. When x is a RasterLayer: format to specify the output format. Either "matrix" or, the default "", in which case a vector is returned

Value

vector or matrix of raster values

See Also

getValuesBlock, getValuesFocal, setValues

Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
r
v <- getValues(r)
length(v)
head(v)
getValues(r, row=10)
```

---

Description

getValuesBlock returns values for a block (rectangular area) of values of a Raster* object.

Usage

```r
## S4 method for signature 'RasterLayer'
getValuesBlock(x, row=1, nrows=1, col=1, ncols=(ncol(x)-col+1), format='')

## S4 method for signature 'RasterBrick'
getValuesBlock(x, row=1, nrows=1, col=1, ncols=(ncol(x)-col+1), lyrs)

## S4 method for signature 'RasterStack'
getValuesBlock(x, row=1, nrows=1, col=1, ncols=(ncol(x)-col+1), lyrs)
```
getValueFocal

Arguments

\( x \)  
Raster* object

\( \text{row} \)  
positive integer. Row number to start from, should be between 1 and \( \text{nrow}(x) \)

\( \text{nrows} \)  
positive integer. How many rows? Default is 1

\( \text{col} \)  
positive integer. Column number to start from, should be between 1 and \( \text{ncol}(x) \)

\( \text{ncols} \)  
positive integer. How many columns? Default is the number of columns left after the start column

\( \text{format} \)  
character. If \( \text{format} = \text{matrix} \), a matrix is returned instead of a vector

\( \text{lyrs} \)  
integer (vector). Which layers? Default is all layers (1:nlayers(\( x \)))

Value

Matrix or vector (if \( x = \text{RasterLayer} \), unless \( \text{format} = \text{matrix} \))

See Also

getValues

Examples

\( r \leftarrow \text{raster(system.file("external/test.grd", package="raster"))} \)
\( b \leftarrow \text{getValuesBlock}(r, \text{row}=100, \text{nrows}=3, \text{col}=10, \text{ncols}=5) \)
\( b \leftarrow \text{matrix}(b, \text{nrow}=3, \text{ncol}=5, \text{byrow}=\text{TRUE}) \)
\( b \)

\( \text{logo} \leftarrow \text{brick(system.file("external/rlogo.grd", package="raster"))} \)
\( \text{getValuesBlock}(\text{logo, row}=35, \text{nrows}=3, \text{col}=50, \text{ncols}=3, \text{lyrs}=2:3) \)
gridDistance

**Arguments**

- **x**: Raster* object
- **row**: Numeric. Row number, should be between 1 and nrow(x). Can be omitted to get all rows
- **nrows**: Numeric. Number of rows, should be a positive integer smaller than row+nrow(x). Should be omitted if row is omitted
- **ngb**: Neighbourhood size. Either a single integer or a vector of two integers (nrow, ncol)
- **names**: logical. If TRUE, the matrix returned has row and column names
- **padValue**: numeric. The value of the cells of the "padded" rows and columns. That is 'virtual' values for cells within a neighbourhood, but outside the raster
- **array**: logical. If TRUE and x has multiple layers, an array is returned instead of a list of matrices
- **...**: additional arguments (none implemented)

**Value**

If x has a single layer, a matrix with one row for each focal cell, and one column for each neighbourhood cell around it.

If x has multiple layers, an array (if array=TRUE) or a list of such matrices (one list element (matrix) for each layer)

**See Also**

- `getValues`, `focal`

**Examples**

```r
r <- raster(nr=5, nc=5, crs='+proj=utm +zone=12')
r[] <- 1:25
as.matrix(r)
getValuesFocal(r, row=1, nrows=2, ngb=3, names=TRUE)
getValuesFocal(stack(r,r), row=1, nrows=1, ngb=3, names=TRUE, array=TRUE)
```

**Description**

The function calculates the distance to cells of a RasterLayer when the path has to go through the centers of neighboring raster cells (currently only implemented as a 'queen' case in which cells have 8 neighbors).

The distance is in meters if the coordinate reference system (CRS) of the RasterLayer is longitude/latitude (+proj=longlat) and in the units of the CRS (typically meters) in other cases.

Distances are computed by summing local distances between cells, which are connected with their neighbours in 8 directions.
Usage

```r
## S4 method for signature 'RasterLayer'
gridDistance(x, origin, omit=NULL, filename="", ...)
```

Arguments

- `x`: RasterLayer
- `origin`: value(s) of the cells from which the distance is calculated
- `omit`: value(s) of the cells which cannot be traversed (optional)
- `filename`: character. output filename (optional)
- `...`: additional arguments as for `writeRaster`

Details

If the RasterLayer to be processed is big, it will be processed in chunks. This may lead to errors in the case of complex objects spread over different chunks (meandering rivers, for instance). You can try to solve these issues by varying the chunk size, see function `setOptions()`.

Value

RasterLayer

Author(s)

Jacob van Etten and Robert J. Hijmans

See Also

See `distance` for 'as the crow flies' distance. Additional distance measures and options (directions, cost-distance) are available in the 'gdistance' package.

Examples

```r
#world lon/lat raster
r <- raster(ncol=10,nrow=10)
r[] <- 1
r[48] <- 2
r[66:68] <- 3
d <- gridDistance(r,origin=2,omit=3)
plot(d)

#UTM small area
projection(r) <- "+proj=utm +zone=15 +ellps=GRS80 +datum=NAD83 +units=m +no_defs"
d <- gridDistance(r,origin=2,omit=3)
plot(d)
```
**hdr**

*Header files*

**Description**

Write header files to use together with raster binary files to read the data in other applications.

**Usage**

```r
hdr(x, format, extension='wld')
```

**Arguments**

- `x`: RasterLayer or RasterBrick object associated with a binary values file on disk
- `format`: Type of header file: 'VRT', 'BIL', 'ENVI', 'ErdasRaw', 'IDRISI', 'SAGA', 'RASTER', 'WORLDFILE', 'PRJ'
- `extension`: File extension, only used with an ESRI worldfile (format='WORLDFILE')

**Details**

The RasterLayer object must be associated with a file on disk.

You can use `writeRaster` to save an existing file in another format. But if you have a file in a 'raster' format (or similar), you can also only export a header file, and use the data file (.gri) that already exists. The function can write a VRT (GDAL virtual raster) header (.vrt); an ENVI or BIL header (.hdr) file; an Erdas Raw (.raw) header file; an IDRISI (.rdc) or SAGA (.sgrd). This (hopefully) allows for reading the binary data (.gri), perhaps after changing the file extension, in other programs such as ENVI or ArcGIS.

**See Also**

`writeRaster`, `writeGDAL`

**Examples**

```r
r <- raster(system.file("external/test.grd", package="raster"))
r <- writeRaster(r, filename='export.grd', overwrite=TRUE)
hdr(r, format="ENVI")
```
head

Show the head or tail of a Raster* object

Description

Show the head (first rows/columns) or tail (last rows/columns) of the cell values of a Raster* object.

Usage

head(x, ...)
tail(x, ...)

Arguments

x

Raster* object

...  

Additional arguments: rows=10 and cols=20, to set the maximum number of rows and columns that are shown. For RasterStack and RasterBrick objects there is an additional argument lyr

Value

matrix

See Also

goodValuesBlock

Examples

r <- raster(nrow=25, ncol=25)
r[] = 1:ncell(r)
head(r)
tail(r, cols=10, rows=5)

hillShade

Hill shading

Description

Compute hill shade from slope and aspect layers (both in radians). Slope and aspect can be computed with function terrain.

A hill shade layer is often used as a backdrop on top of which another, semi-transparent, layer is drawn.
Usage

```r
hillShade(slope, aspect, angle=45, direction=0, filename='', normalize=FALSE, ...)
```

Arguments

- `slope`: RasterLayer object with slope values (in radians)
- `aspect`: RasterLayer object with aspect values (in radians)
- `angle`: The elevation angle of the light source (sun), in degrees
- `direction`: The direction (azimuth) angle of the light source (sun), in degrees
- `filename`: Character. Optional filename
- `normalize`: Logical. If TRUE, values below zero are set to zero and the results are multiplied with 255
- ...: Standard additional arguments for writing RasterLayer files

Author(s)

Andrew Bevan, Robert J. Hijmans

References

See Also

terrain

Examples

```r
## Not run:
alts <- getData('alt', country='CHE')
slope <- terrain(alts, opt='slope')
aspect <- terrain(alts, opt='aspect')
hill <- hillShade(slope, aspect, 40, 270)
plot(hill, col=grey(0:100/100), legend=FALSE, main='Switzerland')
plot(alts, col=rainbow(25, alpha=0.35), add=TRUE)

## End(Not run)
```
Description

Create a histogram of the values of a RasterLayer. For large datasets a sample is used.

Usage

```r
## S4 method for signature 'Raster'
hist(x, layer, maxpixels=100000, plot=TRUE, main, ...)
```

Arguments

- `x`: Raster* object
- `layer`: integer (or character) to indicate layer number (or name). Can be used to subset the layers to plot in a multilayer Raster* object.
- `maxpixels`: integer. To regularly subsample very large objects.
- `plot`: logical. Plot the histogram or only return the histogram values.
- `main`: character. Main title(s) for the plot. Default is the value of `names`.
- `...`: Additional arguments. See under Methods and at `hist`.

Value

This function is principally used for the side-effect of plotting a histogram, but it also returns an S3 object of class 'histogram' (invisibly if `plot=TRUE`).

See Also

- `pairs`, `boxplot`

Examples

```r
r1 <- raster(nrows=50, ncols=50)
r1 <- setValues(r1, runif(ncell(r1)))
r2 <- setValues(r1, runif(ncell(r1)))
rs <- r1 + r2
rp <- r1 * r2
par(mfrow=c(2,2))
plot(rs, main='sum')
plot(rp, main='product')
hist(rs)
a = hist(rp)
a
```
**Description**

Create an "image" type plot of a RasterLayer. This is an implementation of a generic function in the graphics package. In most cases the `plot` function would be preferable because it produces a legend (and has some additional options).

**Usage**

```r
image(x, ...)  # S4 method for signature 'RasterLayer'
image(x, maxpixels=500000, useRaster=TRUE, ...)

# S4 method for signature 'RasterStackBrick'
image(x, y=1, maxpixels=100000, useRaster=TRUE, main, ...)
```

**Arguments**

- `x` : Raster* object
- `maxpixels` : integer > 0. Maximum number of cells to use for the plot. If maxpixels < ncell(x), sampleRegular is used before plotting
- `useRaster` : If TRUE, the rasterImage function is used for plotting. Otherwise the image function is used. This can be useful if rasterImage does not work well on your system (see note)
- `main` : character. Main plot title
- `...` : Any argument that can be passed to `image` (graphics package)
- `y` : If `x` is a RasterStack or RasterBrick: integer, character (layer name(s)), or missing to select which layer(s) to plot

**Note**

raster uses `rasterImage` from the graphics package. For unknown reasons this does not work on Windows Server and on a few versions of Windows XP. On that system you may need to use argument `useRaster=FALSE` to get a plot.

**See Also**

`plot`, `image`, `contour`

**Examples**

```r
r <- raster(system.file("external/test.grd", package="raster"))
image(r)
```
### inifile  
**Read a .ini file**

**Description**

This function reads '.ini' files. These are text file databases that are organized in [sections] containing pairs of "name = value".

**Usage**

```r
readIniFile(filename, token='=', commenttoken=';', aslist=FALSE, case)
```

**Arguments**

- `filename`: Character. Filename of the .ini file
- `token`: Character. The character that separates the "name" (variable name) from the "value"
- `commenttoken`: Character. This token and everything that follows on the same line is considered a 'comment' that is not for machine consumption and is ignored in processing
- `aslist`: Logical. Should the values be returned as a list
- `case`: Optional. Function that operates on the text, such as toupper or tolower

**Details**

This function allows for using inistrings that have "=" as part of a value (but the token cannot be part of the 'name' of a variable!). Sections can be missing.

**Value**

A n*3 matrix of characters with columns: section, name, value; or a list if aslist=TRUE.

---

### initialize  
**Initialize a Raster object with values**

**Description**

Create a new RasterLayer with values reflecting a cell property: 'x', 'y', 'col', 'row', or 'cell'. Alternatively, a function can be used. In that case, cell values are initialized without reference to pre-existing values. E.g., initialize with a random number (fun=runif). While there are more direct ways of achieving this for small objects (see examples) for which a vector with all values can be created in memory, the init function will also work for Raster* objects with many cells.

**Usage**

```r
init(x, fun, filename="", ...)
```
Arguments

x  Raster* object
fun function to be applied. This must be a function that can take the number of
cells as a single argument to return a vector of values with a length equal to the
number of cells, such as fun=runif. You can also supply one of the following
character values: 'x', 'y', 'row', 'col', or 'cell' to get the x or coordinate, row,
col or cell number
filename character. Optional output filename
...
Additional arguments as for writeRaster

Value

RasterLayer

Note

For backwards compatibility, the character values valid for fun can also be passed as named argu-
ment v

Examples

r <- raster(ncols=36, nrows=18)
x <- init(r, fun='cell')
y <- init(r, fun=runif)

# there are different ways to set all values to 1
# for large rasters:
set1f <- function(x)(rep(1, x))
z1 <- init(r, fun=set1f, filename='test.grd', overwrite=TRUE)

# This is equivalent to (but not memory safe):
z2 <- setValues(r, rep(1, ncell(r)))
# or
r[] <- rep(1, ncell(r))
# or
r[] <- 1
**Description**

Make a RasterLayer with interpolated values using a fitted model object of classes such as 'gstat' (gstat package) or 'Krige' (fields package). That is, these are models that have location ('x' and 'y', or 'longitude' and 'latitude') as independent variables. If x and y are the only independent variables provide an empty (no associated data in memory or on file) RasterLayer for which you want predictions. If there are more spatial predictor variables provide these as a Raster* object in the first argument of the function. If you do not have x and y locations as implicit predictors in your model you should use `predict` instead.

**Usage**

```r
## S4 method for signature 'Raster'
interpolate(object, model, filename="", fun=predict, xyOnly=TRUE, xyNames=c('x', 'y'), ext=NULL, const=NULL, index=1, na.rm=TRUE, debug.level=1, ...)
```

**Arguments**

- `object`: Raster* object
- `model`: model object
- `filename`: character. Output filename (optional)
- `fun`: function. Default value is 'predict', but can be replaced with e.g. 'predict.se' (depending on the class of the model object)
- `xyOnly`: logical. If TRUE, values of the Raster* object are not considered as co-variables; and only x and y (longitude and latitude) are used. This should match the model
- `xyNames`: character. variable names that the model uses for the spatial coordinates. E.g., c('longitude', 'latitude')
- `ext`: Extent object to limit the prediction to a sub-region of x
- `const`: data.frame. Can be used to add a constant for which there is no Raster object for model predictions. This is particulary useful if the constant is a character-like factor value
- `index`: integer. To select the column if 'predict.model' returns a matrix with multiple columns
- `na.rm`: logical. Remove cells with NA values in the predictors before solving the model (and return NA for those cells). In most cases this will not affect the output. This option prevents errors with models that cannot handle NA values
- `debug.level`: for gstat models only. See ?
- `...`: additional arguments passed to the predict.'model' function

**Value**

Raster* object

**See Also**

`predict, predict.gstat, Tps`
Examples

```r
## Not run:
## Thin plate spline interpolation with x and y only
# some example data
r <- raster(system.file("external/test.grd", package="raster"))
ra <- aggregate(r, 10)
xy <- data.frame(xyFromCell(ra, 1:ncell(ra)))
v <- getValues(ra)

##### Thin plate spline model
library(fields)
tps <- Tps(xy, v)
p <- raster(r)

# use model to predict values at all locations
p <- interpolate(p, tps)
p <- mask(p, r)

plot(p)
## change the fun from predict to fields::predictSE to get the TPS standard error
se <- interpolate(p, tps, fun=predictSE)
se <- mask(se, r)
plot(se)

## another variable; let's call it elevation
elevation <- (init(r, 'x') * init(r, 'y')) / 100000000
names(elevation) <- 'elev'
elevation <- mask(elevation, r)

z <- extract(elevation, xy)

# add as another independent variable
xyz <- cbind(xy, z)
tps2 <- Tps(xyz, v)
p2 <- interpolate(elevation, tps2, xyOnly=FALSE)

# as a linear covariate
tps3 <- Tps(xy, v, Z=z)

# Z is a separate argument in Krig.predict, so we need a new function
# Internally (in interpolate) a matrix is formed of x, y, and elev (Z)

pfun <- function(model, x, ...) {
  predict(model, x[,1:2], Z=x[,3], ...)
}
p3 <- interpolate(elevation, tps3, xyOnly=FALSE, fun=pfun)

##### gstat examples
library(gstat)
data(meuse)

## inverse distance weighted (IDW)
```
intersect

Intersect

Description

It depends on the classes of the x and y what is returned.

If x is a Raster* object the extent of y is used, irrespective of the class of y, and a Raster* is returned. This is equivalent to crop.
If `x` is a Spatial* object, a new Spatial* object is returned. If `x` or `y` has a data.frame, these are also returned (after merging if necessary) as part of a Spatial*DataFrame, and this is how `intersect` is different from `rgeos::gIntersection` on which it depends.

Intersecting SpatialPoints* with SpatialPoints* uses the extent (bounding box) of `y` to get the intersection. Intersecting of SpatialPoints* and SpatialLines* is not supported because of numerical inaccuracies with that. You can use `buffer`, to create SpatialPolygons* from SpatialLines* and use that in `intersect`. Or try `gIntersection`.

**Usage**

```r
## S4 method for signature 'Extent,ANY'
intersect(x, y)

## S4 method for signature 'Raster,ANY'
intersect(x, y)

## S4 method for signature 'SpatialPoints,ANY'
intersect(x, y)

## S4 method for signature 'SpatialPolygons,SpatialPolygons'
intersect(x, y)

## S4 method for signature 'SpatialPolygons,SpatialLines'
intersect(x, y)

## S4 method for signature 'SpatialPolygons,SpatialPoints'
intersect(x, y)

## S4 method for signature 'SpatialLines,SpatialPolygons'
intersect(x, y)

## S4 method for signature 'SpatialLines,SpatialLines'
intersect(x, y)
```

**Arguments**

- `x`  
  - Extent, Raster*, SpatialPolygons*, SpatialLines* or SpatialPoints* object

- `y`  
  - same as for `x`

**Value**

- if `x` is an Extent object: Extent
- if `x` is a Raster* object: Raster*
- if `x` is a SpatialPoints* object: SpatialPoints*
- if `x` is a SpatialPolygons* object: SpatialPolygons*
- if `x` is a SpatialLines* object and if `y` is a SpatialLines* object: SpatialPoints*
- if `x` is a SpatialLines* object and if `y` is a SpatialPolygons* object: SpatialLines*
isLonLat

See Also

union, extent, crop

Examples

e1 <- extent(-10, 10, -20, 20)
e2 <- extent(0, 20, -40, 5)
intersect(e1, e2)

#SpatialPolygons
if (require(rgdal) & require(rgdal)) {
p <- shapefile(system.file("external/lux.shp", package="raster"))
b <- as(extent(6, 6.4, 49.75, 50), 'SpatialPolygons')
projection(b) <- projection(p)
i <- intersect(p, b)
plot(p)
plot(b, add=TRUE, col='red')
plot(i, add=TRUE, col='blue', lwd=2)
}

isLonLat(x) Is this longitude/latitude data?

Description

Test whether a Raster* or other object has a longitude/latitude coordinate reference system (CRS) by inspecting the PROJ.4 coordinate reference system description. couldBeLonLat also returns TRUE if the CRS is NA but the x coordinates are within -365 and 365 and the y coordinates are within -90.1 and 90.1.

Usage

isLonLat(x)
couldBeLonLat(x, warnings=TRUE)

Arguments

x Raster* object

warnings logical. If TRUE, a warning is given if the CRS is NA or when the CRS is longitude/latitude but the coordinates do not match that

Value

Logical
Examples

```
r <- raster()
isLonLat(r)
projection(r) <- "+proj=lcc +lat_1=48 +lat_2=33 +lon_0=-100 +ellps=WGS84"
isLonLat(r)
```

Description

Export raster data to a KML file and an accompanying PNG image file. Multi-layer objects can be used to create an animation. The function attempts to combine these into a single (and hence more convenient) KMZ file (a zip file containing the KML and PNG files).

See package plotKML for more advanced functionality.

Usage

```r
KML(x, filename, col=rev(terrain.colors(255)),
    colNA=NA, maxpixels=100000, blur=1, zip='', overwrite=FALSE, ...)
```

```r
KML(x, filename, time=NULL, col=rev(terrain.colors(255)),
    colNA=NA, maxpixels=100000, blur=1, zip='', overwrite=FALSE, ...)
```

```r
KML(x, filename, zip='', overwrite=FALSE, ...)
```

Arguments

- **x**: Raster* object
- **filename**: output filename
- **time**: character vector with time labels for multilayer objects. The length of this vector should be `nlayers(x)` to indicate "when" or `nlayers(x)+1` to indicate "begin-end"
- **col**: color scheme to be used (see `image`)
- **colNA**: The color to use for the background (default is transparent)
- **maxpixels**: maximum number of pixels. If `ncell(raster) > maxpixels`, `sampleRegular` is used to reduce the number of pixels
- **blur**: Integer (default=1). Higher values help avoid blurring of isolated pixels (at the expense of a png file that is `blur^2` times larger)
- **zip**: If there is no zip program on your path (on windows), you can supply the full path to a zip.exe here, in order to make a KMZ file
- **overwrite**: logical. If TRUE, overwrite the file if it exists
- **...**: If `x` is a Raster* object, additional arguments that can be passed to `image`
Value

None. Used for the side-effect files written to disk.

Author(s)

This function was adapted for the raster package by Robert J. Hijmans, with ideas from Tony Fischbach, and based on functions in the maptools package by Duncan Golicher, David Forrest and Roger Bivand.

Examples

```r
# Not run:
# Meuse data from the sp package
data(meuse.grid)
b <- rasterFromXYZ(meuse.grid)
projection(b) <- "+init=epsg:28992"
# transform to longitude/latitude
p <- projectRaster(b, crs="+proj=longlat +datum=WGS84", method='ngb')
KML(p, file='meuse.kml')
```

```
## End(Not run)
```

Description

Create a RasterBrick with a Boolean layer for each class (value, or subset of the values) in a RasterLayer. For example, if the cell values of a RasterLayer indicate what vegetation type they are, this function will create a layer (presence/absence; dummy variable) for each of these classes. Classes and cell values are always truncated to integers.

You can supply a second spatially overlapping RasterLayer with larger cells (do not use smaller cells!). In this case the cell values are counts for each class. A similar result might be obtained more efficiently by using layerize with a single RasterLayer followed by `aggregate(x, , sum)`.

Usage

```r
## S4 method for signature 'RasterLayer,missing'
layerize(x, classes=NULL, falseNA=FALSE, filename='', ...)

## S4 method for signature 'RasterLayer,RasterLayer'
layerize(x, y, classes=NULL, filename='', ...)
```
layerStats

Arguments

**x**  
RasterLayer

**y**  
RasterLayer or missing

**classes**  
numeric. The values (classes) for which layers should be made. If NULL all classes are used

**falseNA**  
logical. If TRUE, cells that are not of the class represented by a layer are NA rather then FALSE

**filename**  
character. Output filename (optional)

...  
Additional arguments as for writeRaster

Value

RasterBrick

Examples

```
r <- raster(nrow=36, ncol=72)
r[] <- round(runif(ncell(r))*5)
r[1:5] <- NA
b <- layerize(r)

r2 <- raster(nrow=10, ncol=10)
b2 <- layerize(r, r2)
```

layerStats  

*Correlation and (weighted) covariance*

Description

Compute correlation and (weighted) covariance for multi-layer Raster objects. Like cellStats this function returns a few values, not a Raster* object (see Summary-methods for that).

Usage

```
layerStats(x, stat, w, asSample=TRUE, na.rm=FALSE, ...)
```

Arguments

**x**  
RasterStack or RasterBrick for which to compute a statistic

**stat**  
Character. The statistic to compute: either 'cov' (covariance), 'weighted.cov' (weighted covariance), or 'pearson' (correlation coefficient)

**w**  
RasterLayer with the weights (should have the same extent, resolution and number of layers as x) to compute the weighted covariance

**asSample**  
Logical. If TRUE, the statistic for a sample (denominator is n-1) is computed, rather than for the population (denominator is n)

**na.rm**  
Logical. Should missing values be removed?

...  
Additional arguments (none implemented)
Value

List with two items: the correlation or (weighted) covariance matrix, and the (weighted) means.

Author(s)

Jonathan A. Greenberg & Robert Hijmans. Weighted covariance based on code by Mort Canty

References

For the weighted covariance:

See Also

cellStats, cov.wt, weighted.mean

Examples

```r
b <- brick(system.file("external/rlogo.grd", package="raster"))
layerStats(b, 'pearson')
layerStats(b, 'cov')

# weigh by column number
w <- init(b, v='col')
layerStats(b, 'weighted.cov', w=w)
```

Description

Local functions for two RasterLayer objects (using a focal neighborhood)

Usage

```r
## S4 method for signature 'RasterLayer,RasterLayer'
localFun(x, y, ngb=5, fun, filename='', ...)
Arguments

- `x`: RasterLayer or RasterStack/RasterBrick
- `y`: object of the same class as `x`, and with the same number of layers
- `ngb`: integer. rectangular neighbourhood size. Either a single integer or a vector of two integers (rows, cols), such as c(3,3) to have a 3 x 3 focal window
- `fun`: function
- `filename`: character. Output filename (optional)
- `...`: additional arguments as for `writeRaster`

Value

RasterLayer

Note

The first two arguments that `fun` needs to accept are vectors representing the local cells of RasterLayer `x` and `y` (each of length `ngb` * `ngb`). It also must have an ellipsis (`.`) argument

See Also

corLocal, localFun

Examples

```r
set.seed(0)
b <- stack(system.file("external/rlogo.grd", package="raster"))
x <- flip(b[[2]], 'y') + runif(ncell(b))
y <- b[[1]] + runif(ncell(b))

f <- localFun(x, y, fun=cor)

## Not run:
# local regression:
rfun <- function(x, y, ...) {
  m <- lm(y~x)
  # return R^2
  summary(m)$r.squared
}

ff <- localFun(x, y, fun=rfun)
plot(f, ff)

## End(Not run)
```
Description

The following logical (boolean) operators are available for computations with RasterLayer objects:

&  | |  and  |

The following functions are available with a Raster* argument:

is.na, is.nan, is.finite, is.infinite

Value

A Raster object with logical (TRUE/FALSE values)

Note

These are convenient operators/functions that are most useful for relatively small RasterLayers for which all the values can be held in memory. If the values of the output RasterLayer cannot be held in memory, they will be saved to a temporary file. In that case it could be more efficient to use calc instead.

See Also

Math-methods, overlay, calc

Examples

```r
r <- raster(ncols=10, nrows=10)
r[] <- runif(ncell(r)) * 10
r1 <- r < 3 | r > 10
r2 <- !r1
r3 <- r >= 3 & r <= 6
r4 <- r2 == r3
r[r>3] <- NA
r5 <- is.na(r)
r[r][1:5]
r1[r][1:5]
r2[r][1:5]
r3[r][1:5]
```
Description

Create a new Raster* object that has the same values as x, except for the cells that are NA (or other maskvalue) in a 'mask'. These cells become NA (or other updatevalue). The mask can be either another Raster* object of the same extent and resolution, or a Spatial* object (e.g. SpatialPolygons) in which case all cells that are not covered by the Spatial object are set to updatevalue. You can use inverse=TRUE to set the cells that are not NA (or other maskvalue) in the mask, or not covered by the Spatial* object, to NA (or other updatevalue).

Usage

```r
## S4 method for signature 'RasterLayer,RasterLayer'
mask(x, mask, filename="", inverse=FALSE,
     maskvalue=NA, updatevalue=NA, updateNA=FALSE, ...)

## S4 method for signature 'RasterStackBrick,RasterLayer'
mask(x, mask, filename="", inverse=FALSE,
     maskvalue=NA, updatevalue=NA, updateNA=FALSE, ...)

## S4 method for signature 'RasterLayer,RasterStackBrick'
mask(x, mask, filename="", inverse=FALSE,
     maskvalue=NA, updatevalue=NA, updateNA=FALSE, ...)

## S4 method for signature 'RasterStackBrick,RasterStackBrick'
mask(x, mask, filename="", inverse=FALSE,
     maskvalue=NA, updatevalue=NA, updateNA=FALSE, ...)

## S4 method for signature 'Raster,Spatial'
mask(x, mask, filename="", inverse=FALSE,
     updatevalue=NA, updateNA=FALSE, ...)
```

Arguments

- **x**: Raster* object
- **mask**: Raster* object or a Spatial* object
- **filename**: character. Optional output filename
- **inverse**: logical. If TRUE, areas on mask that are _not_ NA are masked. This option is only relevant if jcodemaskvalue=NA
- **maskvalue**: numeric. The value in mask that indicates the cells of x that should become maskvalue (default = NA)
- **updatevalue**: numeric. The value that cells of x should become if they are not covered by mask (and not NA)
Value matching for Raster* objects

**Description**

match returns a Raster* object with the position of the matched values. The cell values are the index of the table argument.

%in% returns a logical Raster* object indicating if the cells values were matched or not.

**Usage**

```r
match(x, table, nomatch = NA_integer_, incomparables = NULL)
```

x %in% table

**Arguments**

- **x**: Raster* object
- **table**: vector of the values to be matched against
- **nomatch**: the value to be returned in the case when no match is found. Note that it is coerced to integer
- **incomparables**: a vector of values that cannot be matched. Any value in x matching a value in this vector is assigned the nomatch value. For historical reasons, FALSE is equivalent to NULL.
Value

Raster* object

See Also

calc, match

Examples

```r
r <- raster(nrow=10, ncol=10)
r[] <- 1:100
m <- match(r, c(5:10, 50:55))
n <- r %in% c(5:10, 50:55)
```

Description

Generic mathematical functions that can be used with a Raster* object as argument:

"abs", "sign", "sqrt", "ceiling", "floor", "trunc", "cummax", "cummin",
"cumprod", "cumsum", "log", "log10", "log2", "log1p", "acos", "acosh", "asin",
"asinh", "atan", "atanh", "exp", "expm1", "cos", "cosh", "sin", "sinh", "tan", "tanh".

Note

You can use the, somewhat more flexible, function calc instead of the Math-methods.

See Also

Arith-methods, calc, overlay, atan2

Examples

```r
r1 <- raster(nrow=10, ncol=10)
r1 <- setValues(r1, runif(ncell(r1))) * 10
r2 <- sqrt(r1)
s <- stack(r1, r2) - 5
b <- abs(s)
```
merge

**Merge Raster\* objects**

Description

Merge Raster\* objects to form a new Raster object with a larger spatial extent. If objects overlap, the values get priority in the same order as the arguments, but NA values are ignored (except when overlap=FALSE). See `subs` to merge a Raster\* object and a data.frame.

Usage

```r
## S4 method for signature 'Raster,Raster'
merge(x, y, ..., tolerance=0.05, filename="", overlap=TRUE, ext=NULL)

## S4 method for signature 'RasterStackBrick,missing'
merge(x, ..., tolerance=0.05, filename="", ext=NULL)

## S4 method for signature 'Extent,ANY'
merge(x, y, ...)
```

Arguments

- **x** Raster\* or Extent object
- **y** Raster\* if x is a Raster\* object (or missing). If x is an Extent, y can be an Extent or object from which an Extent can be extracted
- **...** additional Raster or Extent objects (and/or arguments for writing files as in `writeRaster`)
- **tolerance** numeric. permissible difference in origin (relative to the cell resolution). See `all.equal`
- **filename** character. Output filename (optional)
- **overlap** logical. If FALSE values of overlapping objects are based on the first layer, even if they are NA
- **ext** Extent object (optional) to limit the output to that extent

Details

The Raster objects must have the same origin and resolution. In areas where the Raster objects overlap, the values of the Raster object that is first in the sequence of arguments will be retained. If you would rather use the average of cell values, or do another computation, you can use `mosaic` instead of `merge`.

Value

RasterLayer or RasterBrick
**metadata**

**Examples**

```r
r1 <- raster(xmn=-150, ymn=60, ncols=30, nrows=30)
r1[] <- 1:ncell(r1)
r2 <- raster(xmn=-100, xmx=-50, ymx=50, ymn=30)
res(r2) <- c(xres(r1), yres(r1))
r2[] <- 1:ncell(r2)
rm <- merge(r1, r2)

# if you have many RasterLayer objects in a list
# you can use do.call:
x <- list(r1, r2)
# add arguments such as filename
# x$filename <- 'test.tif'
m <- do.call(merge, x)
```

---

**Description**

Get or set a metadata to a Raster object

**Usage**

```r
metadata(x)
metadata(x) <- value
```

**Arguments**

- **x** Raster* object
- **value** list with named elements. Each element may be another list of named elements (but these nested lists are not allowed to be lists themselves)

**Value**

Raster* object or list

**Note**

The metadata can contain single values or vectors of basic data types (character, integer, numeric) and Date. Some other types may also be supported. You cannot use a matrix or data.frame as a meta-data element.
modal

**Examples**

```r
r <- raster(nc=10, nr=10)
r[] <- 1:cell(r)

m <- list(wave=list(a=1, b=2, c=c('cool', 'important')),
           that=list(red='44', blue=1:5,
                      days=as.Date(c('2014-1-15', '2014-2-15'))),
           this='888 miles from here', today=NA)

metadata(r) <- m
x <- writeRaster(r, 'test.grd', overwrite=TRUE)
metax <- metadata(x)

identical(metax, m)

## Not run:
# nested too deep
badmeta1 <- list(wave=list(a=1, b=2, c='x'),
                 that=list(red='44', blue=list(bad=5)))
metadata(r) <- badmeta1

# missing names
badmeta2 <- list(wave=list(1, 2, c='x'),
                 that=list(red='44', blue=14),
                 this='8m')
metadata(r) <- badmeta2

# matrix not allowed
badmeta3 <- list(wave=list(a=1, b=matrix(1:4, ncol=2), c='x'),
                 that=list(red='4'))
metadata(r) <- badmeta3

## End(Not run)
```

**modal**  
modal value

**Description**

Compute the mode for a vector of numbers, or across raster layers. The mode, or modal value, is the most frequent value in a set of values.

**Usage**

```r
## S4 method for signature 'ANY'
modal(x, ..., ties='random', na.rm=FALSE, freq=FALSE)

## S4 method for signature 'Raster'
modal(x, ..., ties='random', na.rm=FALSE, freq=FALSE)
```

**Arguments**

- `x` vector of numbers (typically integers), characters, logicals, or factors, or a Raster* object
mosaic

... additional argument of the same type as x

ties character. Indicates how to treat ties. Either 'random', 'lowest', 'highest', 'first', or 'NA'

na.rm logical. If TRUE, NA values are ignored. If FALSE, NA is returned if x has any NA values

freq return the frequency of the modal value, instead of the modal value

Value

vector or RasterLayer. The vector has length 1 and is of the same type as x, except when x is a factor and additional arguments (values) are supplied, in which case the values are coerced to characters and a character value is returned.

Examples

data <- c(0,1,2,3,3,3,3,4,4,4,5,5,6,7,8,9,NA)
modal(data, na.rm=TRUE)

mosaic

Merge Raster* objects using a function for overlapping areas

Description

Mosaic Raster* objects to form a new object with a larger spatial extent. A function is used to compute cell values in areas where layers overlap (in contrast to the merge function which uses the values of the 'upper' layer). All objects must have the same origin, resolution, and coordinate reference system.

Usage

## S4 method for signature 'Raster,Raster'
mosaic(x, y, ..., fun, tolerance=0.05, filename="")

Arguments

x Raster* object

y Raster* object

... Additional Raster or Extent objects (and/or arguments for writing files as in writeRaster)

fun Function. E.g. mean, min, or max. Must be a function that accepts a 'na.rm' argument

tolerance Numeric. permissible difference in origin (relative to the cell resolution). See all.equal

filename Character. Output filename (optional)
movingFun

Details

The Raster objects must have the same origin and resolution.

Value

RasterLayer or RasterBrick object.

See Also

merge, extend

Examples

r <- raster(ncol=100, nrow=100)
r1 <- crop(r, extent(-10, 11, -10, 11))
r2 <- crop(r, extent(0, 20, 0, 20))
r3 <- crop(r, extent(9, 30, 9, 30))

r1[] <- 1:ncell(r1)
r2[] <- 1:ncell(r2)
r3[] <- 1:ncell(r3)

m1 <- mosaic(r1, r2, r3, fun=mean)

s1 <- stack(r1, r1+2)
s2 <- stack(r2, r2/2)
s3 <- stack(r3, r3*4)
m2 <- mosaic(s1, s2, s3, fun=min)

# if you have a list of Raster objects, you can use do.call
x <- list(r1, r2, r3)
names(x)[1:2] <- c('x', 'y')
x$fun <- mean
x$na.rm <- TRUE

y <- do.call(mosaic, x)

movingFun(x, n, fun=mean, type='around', circular=FALSE, na.rm=FALSE)
Arguments

- **x**: A vector of numbers
- **n**: Size of the 'window', i.e. the number of sequential elements to use in the function
- **fun**: A function like mean, min, max, sum
- **type**: Character. One of 'around', 'to', or 'from'. The choice indicates which values should be used in the computation. The focal element is always used. If type is 'around', the other elements are before and after the focal element. Alternatively, you can select the elements preceding the focal element ('to') or those coming after it 'from'. For example, to compute the movingFun with n=3 for element 5 of a vector; 'around' used elements 4,5,6; 'to' used elements 3,4,5, and 'from' uses elements 5,6,7
- **circular**: Logical. If TRUE, the data are considered to have a circular nature (e.g. months of the year), and the last elements in vector x are used in the computation of the moving function of the first element(s) of the vector, and the first elements are used in the computation of the moving function for the last element(s)
- **na.rm**: Logical. If TRUE, NA values should be ignored (by fun)

Value

Numeric

Author(s)

Robert J. Hijmans, inspired by Diethelm Wuertz' rollFun function in the fTrading package

Examples

```r
movingFun(1:12, 3, mean)
movingFun(1:12, 3, mean, 'to')
movingFun(1:12, 3, mean, 'from')
movingFun(1:12, 3, mean, circular=TRUE)

v <- c(0,1,2,3,3,3,4,4,4,5,5,6,7,7,8,9,NA)
movingFun(v, n=5)
movingFun(v, n=5, na.rm=TRUE)
```

Description

Get or set the names of the layers of a Raster* object
NAvalue

Usage

```r
## S4 method for signature 'Raster'
names(x)

## S4 replacement method for signature 'Raster'
names(x) <- value

## S4 method for signature 'Raster'
labels(object)
```

Arguments

- `x` Raster* object
- `object` Raster* object
- `value` character (vector)

Value

Character

See Also

`nlayers`, `bands`

Examples

```r
r <- raster(ncols=5, nrows=5)
r[] <- 1:ncell(r)
s <- stack(r, r, r)
nlayers(s)
names(s)
names(s) <- c('a', 'b', 'c')
names(s)[2] <- 'hello world'
names(s)
s
labels(s)
```

Description

`NAvalue` returns the value that is used to write NA values to disk (in 'raster' type files). If you set
the NA value of a Raster* object, this value will be interpreted as NA when reading the values from
a file. Values already in memory will not be affected.

If the NA value is smaller than zero, all values smaller or equal to that number will be set to NA.
Usage

NAvalue(x) <- value
NAvalue(x)

Arguments

x A Raster object
value the value to be interpreted as NA; set this before reading the values from the file. Integer values are matched exactly; for decimal values files any value <= the value will be interpreted as NA

Value

Returns or set the NA value used for storage on disk.

Examples

r1 <- raster(system.file("external/rlogo.grd", package="raster"))
r2 <- r1
NAvalue(r2)
NAvalue(r2) <- 255
#plot(r1)
#x11()
#plot(r2)

ncell Number or rows, columns, and cells of a Raster* object

Description

Get the number of rows, columns, or cells of a Raster* object.

Usage

ncol(x)
nrow(x)
ncell(x)
ncol(x) <- value
nrow(x) <- value

Arguments

x a Raster object
value row or column number (integer > 0)
Value

Integer

See Also

dim, extent, res

Examples

```r
r <- raster()
nrow(r)
ncol(r)
nrow(r)
dim(r)

nrow(r) <- 18
ncol(r) <- 36
# equivalent to
dim(r) <- c(18, 36)
```

---

**nlayers**

<table>
<thead>
<tr>
<th>Number of layers</th>
</tr>
</thead>
</table>

Description

Get the number of layers in a Raster* object, typically used with a (multilayer) RasterStack or RasterBrick object

Usage

nlayers(x)

Arguments

x Raster* object

Value

integer

See Also

names
Options

Global options for the raster package

Description

Set, inspect, reset, save a number of global options used by the raster package.

Most of these options are used when writing files to disk. They can be ignored by specific functions if the corresponding argument is provided as an argument to these functions.

The default location is returned by `rasterTmpDir`. It is the same as that of the R temp directory but you can change it (for the current session) with `rasterOptions(tmpdir="path")`.

To permanently set any of these options, you can add them to `<your R installation>/etc/Rprofile.site`. For example, to change the default directory used to save temporary files, add a line like this: `options(rasterTmpDir='c:/temp/')` to that file. All temporary raster files in that folder that are older than 24 hrs are deleted when the raster package is loaded.

Function `tmpDir` returns the location of the temporary files

Usage

```
rasterOptions(format, overwrite, datatype, tmpdir, tmptime, progress, timer, chunksize, maxmemory, todisk, setfileext, tolerance, standardnames, depracatedwarnings, addheader, default=FALSE)
```

tmpDir(create=TRUE)

Arguments

- `format`: character. The default file format to use. See `writeFormats`
- `overwrite`: logical. The default value for overwriting existing files. If TRUE, existing files will be overwritten
- `datatype`: character. The default data type to use. See `dataType`
- `tmpdir`: character. The default location for writing temporary files; See `rasterTmpFile`
- `tmptime`: number > 1. The number of hours after which a temporary file will be deleted. As files are deleted when loading the raster package, this option is only useful if you save this option so that it is loaded when starting a new session

Examples

```
r <- raster(ncols=10, nrows=10)
r[] <- 1:ncell(r)
s <- stack(r, r, r)
nlayers(s)
s <- stack(s,s)
nlayers(s)
s <- dropLayer(s, 2:3)
nlayers(s)
```
Options

progress character. Valid values are "text", "window" and "" (the default in most functions, no progress bar)

timer Logical. If TRUE, the time it took to complete the function is printed

chunksize integer. Maximum number of cells to read/write in a single chunk while processing (chunk by chunk) disk based Raster* objects

maxmemory integer. Maximum number of cells to read into memory. I.e., if a Raster* object has more than this number of cells, canProcessInMemory will return FALSE

todisk logical. For debugging only. Default is FALSE and should normally not be changed. If TRUE, results are always written to disk, even if no filename is supplied (a temporary filename is used)

setfileext logical. Default is TRUE. If TRUE, the file extension will be changed when writing (if known for the file type). E.g. GTiff files will be saved with the .tif extension

tolerance numeric. The tolerance used when comparing the origin and resolution of Raster* objects. Expressed as the fraction of a single cell. This should be a number between 0 and 0.5

standardnames logical. Default is TRUE. Should names be standardized to be syntactically valid names (using make.names)

depracatedwarnings logical. If TRUE (the default) a warning is generated when a depracated (obsolete) function is used

addheader character. If not equal to " " (the default) an additional header file is written when a raster format file (grd/gri) is written. Supported formats are as in hdr

default logical. If TRUE, all options are set to their default values

create logical. If TRUE, the temporary files directory is created if it does not exist

Value

list of the current options (invisibly). If no arguments are provided the options are printed.

options, rasterTmpFile

Examples

## Not run:
rasterOptions()
rasterOptions(chunksize=2e+07)

## End(Not run)
origin

**Origin**

**Description**

Origin returns (or sets) the coordinates of the point of origin of a Raster* object. This is the point closest to (0, 0) that you could get if you moved towards that point in steps of the x and y resolution.

**Usage**

```
origin(x, ...)  
origin(x) <- value  
```

**Arguments**

- **x**: Raster* object
- **value**: numeric vector of length 1 or 2
- **...**: additional arguments. None implemented

**Value**

A vector of two numbers (x and y coordinates), or a changed origin for x.

**See Also**

extent

**Examples**

```
r <- raster(xmn=-0.5, xmx = 9.5, ncols=10)  
origin(r)  
r  
origin(r) <- c(0, 0)  
r
```
Description

Create a new Raster* object, based on two or more Raster* objects. (You can also use a single object, but perhaps `calc` is what you are looking for in that case).

You should supply a function `fun` to set the way that the RasterLayers are combined. The number of arguments in the function must match the number of Raster objects (or take any number). For example, if you combine two RasterLayers you could use multiply: `fun=function(x,y){return(x*y)}` percentage: `fun=function(x,y){return(100 * x / y)}`. If you combine three layers you could use `fun=function(x,y,z){return((x + y) * z)}`

Note that the function must work for vectors (not only for single numbers). That is, it must return the same number of elements as its input vectors. Alternatively, you can also supply a function such as `sum`, that takes `n` arguments (as `...`), and perhaps also has a `na.rm` argument, like in `sum(..., na.rm)`.

If a single multi-layer object is provided, its layers are treated as individual RasterLayer objects if the argument "unstack=TRUE" is used. If multiple objects are provided, they should have the same number of layers, or it should be possible to recycle them (e.g., 1, 3, and 9 layers, which would return a RasterBrick with 9 layers).

Usage

```r
## S4 method for signature 'Raster,Raster'
overlay(x, y, ..., fun, filename=NULL, recycle=TRUE, forcefun=FALSE)

## S4 method for signature 'Raster,missing'
overlay(x, y, ..., fun, filename=NULL, unstack=TRUE, forcefun=FALSE)
```

Arguments

- `x`  
  Raster* object

- `y`  
  Raster* object, or missing (only useful if `x` has multiple layers)

- `...`  
  Additional Raster objects (and/or arguments for writing files as in `writeRaster`)

- `fun`  
  Function to be applied. When using RasterLayer objects, the number of arguments of the function should match the number of Raster objects, or it should take any number of arguments. When using multi-layer objects the function should match the number of layers of the RasterStack/Brick object (unless `unstack=FALSE`)

- `filename`  
  Character. Output filename (optional)

- `recycle`  
  Logical. Should layers from Raster objects with fewer layers be recycled?

- `unstack`  
  Logical. Should layers be unstacked before computation (i.e. does the `fun` refer to individual layers in a multilayer object)?

- `forcefun`  
  Boolean. If `TRUE`, `overlay` will not attempt to internally use `apply` (it is rarely necessary to use this argument)
Details

Instead of the overlay function you can also use arithmetic functions such as *, /, +, - with Raster objects (see examples). In that case you cannot specify an output filename. Moreover, the overlay function should be more efficient when using large data files that cannot be loaded into memory, as the use of the complex arithmetic functions might lead to the creation of many temporary files.

While you can supply functions such as sum or mean, it would be more direct to use the Raster* objects as arguments to those functions (e.g. sum(r1, r2, r3))

See rasterize and extract for "overlays" involving Raster* objects and polygons, lines, or points.

Value

Raster* object

See Also

calc, Arith-methods

Examples

```r
r <- raster(ncol=10, nrow=10)
r1 <- init(r, fun=runif)
r2 <- init(r, fun=runif)
r3 <- overlay(r1, r2, fun=function(x,y){return(x+y)})

# long version for multiplication
r4 <- overlay(r1, r2, fun=function(x,y){x*y})

# use the individual layers of a RasterStack to get a RasterLayer
s <- stack(r1, r2)
r5 <- overlay(s, fun=function(x,y) x*y )
# equivalent to
r5c <- calc(s, fun=function(x) x[1]*x[2] )

# Combine RasterStack and RasterLayer objects (s2 has four layers.
# r1 (one layer) and s (two layers) are recycled)
s2 <- stack(r1, r2, r3, r4)
b <- overlay(r1, s, s2, fun=function(x,y,z){return(x*y*z)} )

# use a single RasterLayer (same as calc function)
r6 <- overlay(r1, fun=sqrt)

# multiplication with more than two layers
# (make sure the number of RasterLayers matches the arguments of 'fun')
r7 <- overlay(r1, r2, r3, r4, fun=function(a,b,c,d){return(a*b*c*d)} )
# equivalent function, efficient if values can be loaded in memory
r8 <- r1 * r2 + r3 * r4

# Also works with multi-layer objects.
s1 <- stack(r1, r2, r3)
x <- overlay(s1, s1, fun=function(x,y)x+y+5)
```
pairs

# in this case the first layer of the shorter object is recycled.
# i.e., s2 is treated as stack(r1, r3, r1)
s2 <- stack(r1, r3)
y <- overlay(s1, s2, fun=sum)

pairs

Pairs plot (matrix of scatterplots)

Description

Pair plots of layers in a RasterStack or RasterBrick. This is a wrapper around graphics function pairs.

Usage

## S4 method for signature 'RasterStackBrick'
pairs(x, hist=TRUE, cor=TRUE, use="pairwise.complete.obs", maxpixels=100000, ...)

Arguments

- **x** RasterBrick or RasterStack
- **hist** Logical. If TRUE a histogram of the values is shown on the diagonal
- **cor** Logical. If TRUE the correlation coefficient is shown in the upper panels
- **use** Argument passed to the cor function
- **maxpixels** Integer. Number of pixels to sample from each layer of large Raster objects
- **...** Additional arguments (only cex and main)

See Also

boxplot, hist, density

Examples

r <- raster(system.file("external/test.grd", package="raster") )
s <- stack(r, 1/r, sqrt(r))
pairs(s)

## Not run:
# to make individual histograms:
hist(r)
# or scatter plots:
plot(r, 1/r)

## End(Not run)
Description

Perspective plot of a RasterLayer. This is an implementation of a generic function in the graphics package.

Usage

```r
## S4 method for signature 'RasterLayer'
persp(x, maxpixels=1e+05, ext=NULL, ...)
```

```r
## S4 method for signature 'RasterStackBrick'
persp(x, y=1, maxpixels=10000, ext=NULL, ...)
```

Arguments

- **x**: Raster* object
- **y**: integer > 0 & <= `nLayers(x)` to select the layer of x if x is a RasterLayer or RasterBrick
- **maxpixels**: integer > 0. Maximum number of cells to use for the plot. If `maxpixels < ncell(x)`, `sampleRegular` is used before plotting
- **ext**: Extent. Van be used to zoom in a region (see also `zoom` and `crop(x, drawExtent())`)
- **...**: Any argument that can be passed to `persp` (graphics package)

See Also

`plot3D, persp, contour, plot`

Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
persp(r)
```
**Description**

Plot (that is, make a map of) the values of a Raster* object, or make a scatterplot of their values.

Points, lines, and polygons can be drawn on top of a map using plot(..., add=TRUE), or with functions like points, lines, polygons

See the rasterVis package for more advanced (trellis/lattice) plotting of Raster* objects.

**Usage**

```r
## S4 method for signature 'Raster,ANY'
plot(x, y, maxpixels=500000, col, alpha=NULL,
     colNA=NA, add=FALSE, ext=NULL, useRaster=TRUE, interpolate=FALSE,
     addfun=NULL, nc, nr, maxnl=16, main, npretty=0, ...)

## S4 method for signature 'Raster,Raster'
plot(x, y, maxpixels=100000, cex, xlab, ylab, nc, nr,
     maxnl=16, main, add=FALSE, gridded=FALSE, ncol=25, nrow=25, ...)
```

**Arguments**

- **x** Raster* object
- **y** If x is a RasterStack or RasterBrick: integer, character (layer name(s)), or missing to select which layer(s) to plot. If missing, all RasterLayers in the RasterStack will be plotted (up to a maximum of 16). Or another Raster* object of the same extent and resolution, to produce a scatter plot of the cell values.
- **maxpixels** integer > 0. Maximum number of cells to use for the plot. If maxpixels < ncell(x), sampleRegular is used before plotting. If gridded=TRUE maxpixels may be ignored to get a larger sample
- **col** A color palette, i.e. a vector of n contiguous colors generated by functions like rainbow, heat.colors, topo.colors, bpy.colors or one or your own making, perhaps using colorRampPalette. If none is provided, rev(terrain.colors(255)) is used unless x has a 'color table'
- **alpha** Number between 0 and 1 to set transparency. 0 is entirely transparent, 1 is not transparent (NULL is equivalent to 1)
- **colNA** The color to use for the background (default is transparent)
- **add** Logical. Add to current plot?
- **ext** An extent object to zoom in a region (see also zoom and crop(x, drawExtent())
- **useRaster** If TRUE, the rasterImage function is used for plotting. Otherwise the image function is used. This can be useful if rasterImage does not work well on your system (see note)
interpolate Logical. Should the image be interpolated (smoothed)? Only used when useRaster = TRUE

addfun Function to add additional items such as points or polygons to the plot (map). Typically containing statements like "points(xy); plot(polygons, add=TRUE)". This is particularly useful to add something to each map when plotting a multi-layer Raster* object.

npretty integer. Number of decimals for pretty lables on the axes

... Graphical parameters. Any argument that can be passed to image.plot and to plot, such as axes=FALSE, main='title', ylab='latitude'

xlab Optional. x-axis label)

ylab Optional. y-axis label)

nc Optional. The number of columns to divide the plotting device in (when plotting multiple layers in a RasterLayer or RasterBrick object)

nr Optional. The number of rows to divide the plotting device in (when plotting multiple layers in a RasterLayer or RasterBrick object)

maxnl integer. Maximum number of layers to plot (for a multi-layer object)

main character. Main plot title

cex Symbol size for scatter plots

gridded logical. If TRUE the scatterplot is gridded (counts by cells)

ncol integer. Number of columns for gridding

nrow integer. Number of rows for gridding

Details

Most of the code for the plot function for a single Raster* object was taken from image.plot (fields package).

Raster objects with a color-table (e.g. a graphics file) are plotted according to that color table.

Note

raster uses rasterImage from the graphics package. For unknown reasons this does not work on Windows Server and on a few versions of Windows XP. On that system you may need to use argument useRaster=FALSE to get a plot.

See Also

The rasterVis package has lattice based methods for plotting Raster* objects (like spplot) red-green-blue plots (e.g. false color composites) can be made with plotRGB barplot, hist, text, persp, contour, pairs
Examples

```r
# RasterLayer
r <- raster(nrows=10, ncols=10)
r <- setValues(r, 1:ncell(r))
plot(r)

e <- extent(r)
plot(e, add=TRUE, col='red', lwd=4)
e <- e / 2
plot(e, add=TRUE, col='red')

# Scatterplot of 2 RasterLayers
r2 <- sqrt(r)
plot(r, r2)
plot(r, r2, gridded=TRUE)

# Multi-layer object (RasterStack / Brick)
s <- stack(r, r2, r/r)
plot(s, 2)
plot(s)

# two objects, different range, one scale:
r[] <- runif(ncell(r))
r2 <- r/2
brks <- seq(0, 1, by=0.1)
b <- length(brks)-1
cols <- rev(terrain.colors(nb))
par(mfrow=c(1,2))
plot(r, breaks=brks, col=cols, lab=breaks=brks, zlim=c(0,1), main='first')
plot(r2, breaks=brks, col=cols, lab=breaks=brks, zlim=c(0,1), main='second')

# breaks and labels
x <- raster(nc=10, nr=10)
x[] <- runif(ncell(x))
breaks <- c(0, 0.25, 0.75, 1)
labels <- c('Low', 'Med.', 'High')
par(mfrow=c(1,1))
plot(x, col=terrain.colors(3), breaks=brks)
plot(x, col=terrain.colors(3), breaks=brks, axis.args=arg)
par(mfrow=c(1,1))

# adding random points to the map
xy <- cbind(-180 + runif(10) * 360, -90 + runif(10) * 180)
points(xy, pch=3, cex=5)

# for SpatialPolygons do
# plot(pols, add=TRUE)
```
# adding the same points to each map of each layer of a RasterStack
fun <- function() {
  points(xy, cex=2)
  points(xy, pch=3, col='red')
}
plot(s, addfun=fun)

plotRGB

Red-Green-Blue plot of a multi-layered Raster object

Description

Make a Red-Green-Blue plot based on three layers (in a RasterBrick or RasterStack). Three layers (sometimes referred to as "bands" because they may represent different bandwidths in the electromagnetic spectrum) are combined such that they represent the red, green and blue channel. This function can be used to make 'true (or false) color images' from Landsat and other multi-band satellite images.

Usage

## S4 method for signature 'RasterStackBrick'
plotRGB(x, r=1, g=2, b=3, scale, maxpixels=500000, stretch=NULL,
  ext=NULL, interpolate=FALSE, colNA='white', alpha, bgalpha, addfun=NULL, zlim=NULL,
  zlimcol=NULL, axes=FALSE, xlab=' ', ylab=' ', asp=NULL, add=FALSE, ...)

Arguments

x RasterBrick or RasterStack
r integer. Index of the Red channel, between 1 and nlayers(x)
g integer. Index of the Green channel, between 1 and nlayers(x)
b integer. Index of the Blue channel, between 1 and nlayers(x)
scale integer. Maximum (possible) value in the three channels. Defaults to 255 or to the maximum value of x if that is known and larger than 255
maxpixels integer > 0. Maximum number of pixels to use
stretch character. Option to stretch the values to increase the contrast of the image: "lin" or "hist"
ext An Extent object to zoom in to a region of interest (see drawExtent)
interpolate logical. If TRUE, interpolate the image when drawing
colNA color for the background (NA values)
alpha transparency. Integer between 0 (transparent) and 255 (opaque)
bgalpha Background transparency. Integer between 0 (transparent) and 255 (opaque)
addfun  Function to add additional items such as points or polygons to the plot (map). See plot
zlim   numeric vector of length 2. Range of values to plot (optional)
zlimcol If NULL the values outside the range of zlim get the color of the extremes of the range. If zlimcol has any other value, the values outside the zlim range get the color of NA values (see colNA)
axes   logical. If TRUE axes are drawn (and arguments such as main="title" will be honored)
xlab   character. Label of x-axis
ylab   character. Label of y-axis
asp    numeric. Aspect (ratio of x and y. If NULL, and appropriate value is computed to match data for the longitude/latitude coordinate reference system, and 1 for planar coordinate reference systems
add    logical. If TRUE add values to current plot
...    graphical parameters as in plot or rasterImage

Author(s)
Robert J. Hijmans; stretch option based on functions by Josh Gray

See Also
plot

Examples
b <- brick(system.file("external/rlogo.grd", package="raster"))
plotRGB(b)
plotRGB(b, 3, 2, 1)
plotRGB(b, 3, 2, 1, stretch=hist)

Description
Calculate the geographic distance between two (sets of) points on the WGS ellipsoid (lonlat=TRUE) or on a plane (lonlat=FALSE). If both sets do not have the same number of points, the distance between each pair of points is given. If both sets have the same number of points, the distance between each point and the corresponding point in the other set is given, except if allpairs=TRUE.

Usage
pointDistance(p1, p2, lonlat, allpairs=FALSE, ...)
pointDistance

Arguments

- **p1**: x and y coordinate of first (set of) point(s), either as c(x, y), matrix(ncol=2), or SpatialPoints*
- **p2**: x and y coordinate of second (set of) second point(s) (like for p1). If this argument is missing, a distance matrix is computed for p1
- **lonlat**: logical. If TRUE, coordinates should be in degrees; else they should represent planar (‘Euclidean’) space (e.g. units of meters)
- **allpairs**: logical. Only relevant if the number of points in x and y is the same. If FALSE the distance between each point in x with the corresponding point in y is returned. If TRUE a full distance matrix is returned
- ... Additional arguments. None implemented

Value

A single value, or a vector, or matrix of values giving the distance in meters (lonlat=TRUE) or map-units (for instance, meters in the case of UTM) If p2 is missing, a distance matrix is returned

Author(s)

Robert J. Hijmans and Jacob van Etten. The distance for longitude/latitude data uses GeographicLib by C.F.F. Karney

distanceFromPoints, distance, gridDistance, spDistsN1. The geosphere package has many additional distance functions and other functions that operate on spherical coordinates

Examples

```r
a <- cbind(c(1,5,55,31),c(3,7,20,22))
b <- cbind(c(4,2,8,65),c(50,-90,20,32))

pointDistance(c(0, 0), c(1, 1), lonlat=FALSE)
pointDistance(c(0, 0), c(1, 1), lonlat=TRUE)
pointDistance(c(0, 0), a, lonlat=TRUE)
pointDistance(a, b, lonlat=TRUE)

# Make a distance matrix
dst <- pointDistance(a, lonlat=TRUE)
# coerce to dist object
dst <- as.dist(dst)
```
predict  Spatial model predictions

Description

Make a Raster object with predictions from a fitted model object (for example, obtained with `lm`, `glm`). The first argument is a Raster object with the independent (predictor) variables. The names in the Raster object should exactly match those expected by the model. This will be the case if the same Raster object was used (via `extract`) to obtain the values to fit the model (see the example). Any type of model (e.g. `glm`, `gam`, `randomForest`) for which a predict method has been implemented (or can be implemented) can be used.

This approach (predict a fitted model to raster data) is commonly used in remote sensing (for the classification of satellite images) and in ecology, for species distribution modeling.

Usage

```r
## S4 method for signature 'Raster'
predict(object, model, filename="", fun=predict, ext=NULL, 
const=NULL, index=1, na.rm=TRUE, inf.rm=FALSE, factors=NULL, 
format, datatype, overwrite=FALSE, progress=' ', ...)"'
```

Arguments

- `object`: Raster* object. Typically a multi-layer type (RasterStack or RasterBrick)
- `model`: fitted model of any class that has a 'predict' method (or for which you can supply a similar method as `fun` argument. E.g. `glm`, `gam`, or `randomForest`
- `filename`: character. Optional output filename
- `fun`: function. Default value is 'predict', but can be replaced with e.g. `predict.se` (depending on the type of model), or your own custom function.
- `ext`: Extent object to limit the prediction to a sub-region of `x`
- `const`: data.frame. Can be used to add a constant for which there is no Raster object for model predictions. Particularly useful if the constant is a character-like factor value for which it is currently not possible to make a RasterLayer
- `index`: integer. To select the column(s) to use if predict.'model' returns a matrix with multiple columns
- `na.rm`: logical. Remove cells with NA values in the predictors before solving the model (and return a NA value for those cells). This option prevents errors with models that cannot handle NA values. In most other cases this will not affect the output. An exception is when predicting with a boosted regression trees model because these return predicted values even if some (or all!) variables are NA
- `inf.rm`: logical. Remove cells with values that are not finite (some models will fail with -Inf/Inf values). This option is ignored when `na.rm=FALSE`
predict

factors  list with levels for factor variables. The list elements should be named with
names that correspond to names in object such that they can be matched. This
argument may be omitted for standard models such as 'glm' as the predict func-
tion will extract the levels from the model object, but it is necessary in some
other cases (e.g. cforest models from the party package)

format  character. Output file type. See writeRaster (optional)
datatype  character. Output data type. See dataType (optional)
overwrite  logical. If TRUE, "filename" will be overwritten if it exists
progress  character. "text", "window", or "" (the default, no progress bar)
...  additional arguments to pass to the predict.'model' function

Value
RasterLayer or RasterBrick

Note
There is a lot of general information about the use of the predict function in the species distribution
modeling vignette of the dismo package.

See Also
Use interpolate if your model has 'x' and 'y' as implicit independent variables (e.g., in kriging).

Examples

# A simple model to predict the location of the R in the R-logo using 20 presence points
# and 50 (random) pseudo-absence points. This type of model is often used to predict
# species distributions. See the dismo package for more of that.

# create a RasterStack or RasterBrick with with a set of predictor layers
logo <- brick(system.file("external/rlogo.grd", package="raster"))
names(logo)

## Not run:
# the predictor variables
par(mfrow=c(2,2))
plotRGB(logo, main='logo')
plot(logo, 1, col=rgb(cbind(0:255,0,0), maxColorValue=255))
plot(logo, 2, col=rgb(cbind(0,0:255,0), maxColorValue=255))
plot(logo, 3, col=rgb(cbind(0,0,0:255), maxColorValue=255))
par(mfrow=c(1,1))

## End(Not run)

# known presence and absence points

v$red <- as.factor(round(v$red/100))
logo$red <- round(logo[[1]]/100)

library(party)
m <- cforest(pa~., control=cforest_unbiased(mtry=3), data=v)
f <- list(levels(v$red))
names(f) <- 'red'

pc <- predict(logo, m, OOB=TRUE, factors=f)

# knn example, using calc instead of predict
library(class)
cl <- factor(c(rep(1, nrow(p)), rep(0, nrow(a))))
train <- extract(logo, rbind(p, a))
k <- calc(logo, function(x) as.integer(as.character(knn(train, x, cl))))

## End(Not run)
Programming

Helper functions for programming

Description

These are low level functions that can be used by programmers to develop new functions. If in doubt, it is almost certain that you do not need these functions as these are already embedded in all other functions in the raster package.

canProcessInMemory is typically used within functions. In the raster package this function is used to determine if the amount of memory needed for the function is available. If there is not enough memory available, the function returns FALSE, and the function that called it will write the results to a temporary file.

readStart opens file connection(s) for reading, readStop removes it.

pbCreate creates a progress bar, pbStep sets the progress, and pbClose closes it.

Usage

canProcessInMemory(x, n=4)
pbCreate(nsteps, progress, style=3, label='Progress', ...)
pbStep(pb, step=NULL, label='')
pbClose(pb, timer)
readStart(x, ...)
readStop(x, ...)
getCluster()
returnCluster()

Arguments

x RasterLayer or RasterBrick object (for connections) or RasterStack object (canProcessInMemory)
n integer. The number of copies of the Raster* object cell values that a function needs to be able to have in memory
nsteps integer. Number of steps the progress bar will make from start to end (e.g. nrow(raster))
progress character. 'text', 'window', or "
style style for text progress bar. See txtProgressBar
label character. Label for the window type progress bar
... additional arguments (None implemented, except for 'silent=TRUE' for readStart for files read with gdal, and other arguments passed to gdal.open)

pb progress bar object created with pbCreate
step which step is this ( 1 <= step <= nsteps ). If step is NULL, a single step is taken
timer logical. If TRUE, time to completion will be printed. If missing, the value will be taken from the rasterOptions
projection

Value

`canProcessInMemory`: logical
`closeConnection`: RasterLayer or RasterBrick object
`getCluster`: snow cluster object

Examples

```r
r <- raster(nrow=100, ncol=100)
canProcessInMemory(r, 4)
r <- raster(nrow=100000, ncol=100000)
canProcessInMemory(r, 2)
```

---

**projection**  
Get or set a coordinate reference system (projection)

Description

Get or set the coordinate reference system (CRS) of a Raster* object.

Usage

```r
## S4 method for signature 'ANY'
crs(x, asText=FALSE, ...)
```

```r
crs(x) <- value

projection(x, asText=TRUE)
projection(x) <- value
```

Arguments

- `x`: Raster* or Spatial object
- `asText`: logical. If TRUE, the projection is returned as text. Otherwise a CRS object is returned
- `...`: additional arguments (not implemented)
- `value`: CRS object or a character string describing a projection and datum in the PROJ.4 format

Details

Projections are done by with the PROJ.4 library exposed by rgdal

Value

Raster*, Spatial*, CRS, or character object
Note

crs replaces earlier function projection. For compatibility with sp you can use proj4string instead of crs.

See Also

projectRaster, CRS-class, spTransform-methods, projInfo

Examples

```r
r <- raster()
crs(r)
crs(r) <- "+proj=lcc +lat_1=48 +lat_2=33 +lon_0=-100 +ellps=WGS84"
crs(r)
```

Description

Project the values of a Raster* object to a new Raster* object with another projection (coordinate reference system, CRS). You can do this by providing the new projection as a single argument in which case the function sets the extent and resolution of the new object. To have more control over the transformation, and, for example, to assure that the new object lines up with other datasets, you can provide a Raster* object with the properties that the input data should be projected to.

projectExtent returns a RasterLayer with a projected extent, but without any values. This RasterLayer can then be adjusted (e.g. by setting its resolution) and used as a template 'to' in projectRaster.

Usage

```r
projectRaster(from, to, res, crs, method="bilinear",
               alignOnly=FALSE, over=FALSE, filename="", ...)
```

```r
projectExtent(object, crs)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from</td>
<td>Raster* object</td>
</tr>
<tr>
<td>to</td>
<td>Raster* object with the parameters to which 'from' should be projected</td>
</tr>
<tr>
<td>res</td>
<td>single or (vector of) two numerics. To, optionally, set the output resolution if 'to' is missing</td>
</tr>
<tr>
<td>crs</td>
<td>character or object of class 'CRS'. PROJ.4 description of the coordinate reference system. In projectRaster this is used to set the output CRS if 'to' is missing, or if 'to' has no valid CRS</td>
</tr>
</tbody>
</table>
project raster

method

method used to compute values for the new RasterLayer. Either 'ngb' (nearest neighbor), which is useful for categorical variables, or 'bilinear' (bilinear interpolation; the default value), which is appropriate for continuous variables.

alignOnly

logical. Use to or other parameters only to align the output (i.e. same origin and resolution), but use the projected extent from from

over

logical. If TRUE wrapping around the date-line is turned off. This can be desirable for global data (to avoid mapping the same areas twice) but it is not desirable in other cases

filename

character. Output filename

... additional arguments as for writeRaster

object Raster* object

Details

There are two approaches you can follow to project the values of a Raster object.

1) Provide a crs argument, and, optionally, a res argument, but do not provide a to argument.

2) Create a template Raster with the CRS you want to project to. You can use an existing object, or use projectExtent for this or an existing Raster* object. Also set the number of rows and columns (or the resolution), and perhaps adjust the extent. The resolution of the output raster should normally be similar to that of the input raster. Then use that object as from argument to project the input Raster to. This is the preferred method because you have most control. For example you can assure that the resulting Raster object lines up with other Raster objects.

Projection is performed using the PROJ.4 library accessed through the rgdal package.

One of the best places to find PROJ.4 coordinate reference system descriptions is http://www.spatialreference.org.

You can also consult this page: http://www.remotesensing.org/geotiff/proj_list/ to find the parameter options and names for projections.

Also see projInfo('proj'), projInfo('ellps'), and projInfo('datum') for valid PROJ.4 values.

Value

RasterLayer or RasterBrick object.

Note

Vector (points, lines, polygons) can be transformed with spTransform.

projectExtent does not work very well when transforming projected circumpolar data to (e.g.) longitude/latitude. With such data you may need to adjust the returned object. E.g. do ymax(object) <- 90

Examples

# create a new (not projected) RasterLayer with cellnumbers as values
r <- raster(xmn=-110, xmx=-90, ymn=40, ymx=60, ncols=40, nrows=40)
r <- setValues(r, 1:nCell(r))
projection(r)
# proj.4 projection description
newproj <- "+proj=lcc +lat_1=48 +lat_2=33 +lon_0=-100 +ellps=WGS84"

# we need the rgdal package for this
if (require(rgdal)) {

# simplest approach
pr1 <- projectRaster(r, crs=newproj)

# alternatively also set the resolution
pr2 <- projectRaster(r, crs=newproj, res=20000)

# inverse projection, back to the properties of 'r'
inv <- projectRaster(pr2, r)

# to have more control, provide an existing Raster object, here we create one
# using projectExtent (no values are transferred)
pr3 <- projectExtent(r, newproj)
# Adjust the cell size
res(pr3) <- 20000
# now project
pr3 <- projectRaster(r, pr3)

## Not run:
# using a higher resolution
res(pr1) <- 10000
pr <- projectRaster(r, pr1, method='bilinear')
inv <- projectRaster(pr, r, method='bilinear')
dif <- r - inv
# small difference
plot(dif)

## End(Not run)
}

properties Raster file properties
Description

Properties of the values of the file that a RasterLayer object points to.

dataSize returns the number of bytes used for each value (pixel, grid cell) dataSigned is TRUE for data types that include negative numbers.

Usage

dataSize(object)
dataSigned(object)

Arguments

object Raster* object

Value

varies

See Also

filename

Examples

r <- raster(system.file("external/test.grd", package="raster"))
dataSize(r)
dataSigned(r)
dataType(r)

quantile Raster quantiles

Description

Compute quantiles for the cell values of a RasterLayer. If you want to compute quantiles for each cell across a number of layers, you can use calc(x, fun=quantile).

Usage

quantile(x, ...)

Arguments

x Raster object

... Additional arguments: na.rm=TRUE, ncells=NULL, and additional arguments to the stats::quantile function, see quantile ncells can be used to set the number of cells to be sampled, for very large raster datasets.
Value
A vector of quantiles

See Also
density, cellStats

Examples

```r
r <- raster(ncol=100, nrow=100)
r[] <- rnorm(ncell(r), 0, 50)
quantile(r)
quantile(r, probs = c(0.25, 0.75), type=7, names = FALSE)
```

---

raster

Create a RasterLayer object

Description

Methods to create a RasterLayer object. RasterLayer objects can be created from scratch, a file, an Extent object, a matrix, an 'image' object, or from a Raster*, Spatial*, im (spatstat) asc, kase (adehabitat*), grf (geoR) or kde object.

In many cases, e.g. when a RasterLayer is created from a file, it does (initially) not contain any cell (pixel) values in (RAM) memory, it only has the parameters that describe the RasterLayer. You can access cell-values with `getValues`, `extract` and related functions. You can assign new values with `setValues` and with `replacement`.

For an overview of the functions in the raster package have a look here: raster-package.

Usage

```r
## S4 method for signature 'character'
raster(x, band=1, ...)

## S4 method for signature 'RasterLayer'
raster(x)

## S4 method for signature 'RasterStack'
raster(x, layer=0)

## S4 method for signature 'RasterBrick'
raster(x, layer=0)

## S4 method for signature 'missing'
raster(nrows=180, ncols=360, xmn=-180, xmin=180, ymn=-90, ymx=90,
crs, ext, resolution, vals=NULL)
```
## S4 method for signature 'Extent'
`raster(x, nrows=10, ncols=10, crs=NA, ...)

## S4 method for signature 'matrix'
`raster(x, xmn=0, xmx=1, ymn=0, ymx=1, crs=NA, template=NULL)

## S4 method for signature 'big.matrix'
`raster(x, xmn=0, xmx=1, ymn=0, ymx=1, crs=NA, template=NULL)

## S4 method for signature 'Spatial'
`raster(x, origin, ...)

## S4 method for signature 'SpatialGrid'
`raster(x, layer=1, values=TRUE)

## S4 method for signature 'SpatialPixels'
`raster(x, layer=1, values=TRUE)

### Arguments

- **x**
  - filename (character), Extent, Raster*, SpatialPixels*, SpatialGrid*, object, 'image', matrix, im, or missing. Supported file types are the 'native' raster package format and those that can be read via rgdal (see `readGDAL`

- **band**
  - integer. The layer to use in a multi-layer file

- **...**
  - Additional arguments, see Details

- **layer**
  - integer. The layer (variable) to use in a multi-layer file, or the layer to extract from a RasterStack/Brick or SpatialPixelsDataFrame or SpatialGridDataFrame. An empty RasterLayer (no associated values) is returned if layer=0

- **values**
  - logical. If TRUE, the cell values of 'x' are copied to the RasterLayer object that is returned

- **nrows**
  - integer > 0. Number of rows

- **ncols**
  - integer > 0. Number of columns

- **xmn**
  - minimum x coordinate (left border)

- **xmx**
  - maximum x coordinate (right border)

- **ymn**
  - minimum y coordinate (bottom border)

- **ymx**
  - maximum y coordinate (top border)

- **ext**
  - object of class Extent. If present, the arguments xmn, xmx, ymn and ynx are ignored

- **crs**
  - character or object of class CRS. PROJ.4 type description of a Coordinate Reference System (map projection). If this argument is missing, and the x coordinates are within -360 .. 360 and the y coordinates are within -90 .. 90, "+proj=longlat +datum=WGS84" is used. Also see under Details if x is a character (filename)

- **resolution**
  - numeric vector of length 1 or 2 to set the resolution (see `res`). If this argument is used, arguments ncols and nrows are ignored

- **vals**
  - optional. Values for the new RasterLayer. Accepted formats are as for `setValues`
origin minimum y coordinate (bottom border)
template Raster* or Extent object used to set the extent (and CRS in case of a Raster* object). If not NULL, arguments xmn, xmx, ymn, ymx and crs (unless template is an Extent object) are ignored

Details

If x is a filename, the following additional variables are recognized:

sub: positive integer. Subdataset number for a file with subdatasets

native: logical. Default is FALSE except when package rgdal is missing. If TRUE, reading and writing of IDRISI, BIL, BSQ, BIP, SAGA, and Arc ASCII files is done with native (raster package) drivers, rather then via rgdal. 'raster' and netcdf format files are always read with native drivers.

RAT: logical. The default is TRUE, in which case a raster attribute table is created for files that have one

offset: integer. To indicate the number of header rows on non-standard ascii files (rarely useful; use with caution)

crs: character. PROJ.4 string to set the CRS. Ignored when the file provides a CRS description that can be interpreted.

If x represents a NetCDF file, the following additional variable is recognized:

varname: character. The variable name, such as 'tasmax' or 'pr'. If not supplied and the file has multiple variables are a guess will be made (and reported)

1var: integer > 0 (default=3). To select the 'level variable' (3rd dimension variable) to use, if the file has 4 dimensions (e.g. depth instead of time)

level: integer > 0 (default=1). To select the 'level' (4th dimension variable) to use, if the file has 4 dimensions, e.g. to create a RasterBrick of weather over time at a certain height.

To use NetCDF files the ncdf4 package needs to be available. It is assumed that these files follow, or are compatible with, the CF-1 convention (The GMT format may also work). If the ncdf file does not have a standard extension (which is used to recognize the file format), you can use argument ncdf=TRUE to indicate the format.

If x is a Spatial or an Extent object, additional arguments are for the method with signature 'missing'

Value

RasterLayer

**Raster-class**

**Raster* classes**
Description

A raster is a database organized as a rectangular grid that is sub-divided into rectangular cells of equal area (in terms of the units of the coordinate reference system). The 'raster' package defines a number of "S4 classes" to manipulate such data.

The main user level classes are RasterLayer, RasterStack and RasterBrick. They all inherit from BasicRaster and can contain values for the raster cells.

An object of the RasterLayer class refers to a single layer (variable) of raster data. The object can point to a file on disk that holds the values of the raster cells, or hold these values in memory. Or it can not have any associated values at all.

A RasterStack represents a collection of RasterLayer objects with the same extent and resolution. Organizing RasterLayer objects in a RasterStack can be practical when dealing with multiple layers; for example to summarize their values (see calc) or in spatial modeling (see predict).

An object of class RasterBrick can also contain multiple layers of raster data, but they are more tightly related. An object of class RasterBrick can refer to only a single (multi-layer) data file, whereas each layer in a RasterStack can refer to another file (or another band in a multi-band file). This has implications for processing speed and flexibility. A RasterBrick should process quicker than a RasterStack (irrespective if values are on disk or in memory). However, a RasterStack is more flexible as a single object can refer to layers that have values stored on disk as well as in memory. If a layer that does not refer to values on disk (they only exists in memory) is added to a RasterBrick, it needs to load all its values into memory (and this may not be possible because of memory size limitations).

Objects can be created from file or from each other with the following functions: raster, brick and stack.

Raster* objects can also be created from SpatialPixels* and SpatialGrid* objects from the sp package using as, or simply with the function raster, brick, or stack. Vice versa, Raster* objects can be coerced into a sp type object with as( , ), e.g. as(x, 'SpatialGridDataFrame'). Common generic methods implemented for these classes include: summary, show, dim, and plot, ...

[ is implemented for RasterLayer.

The classes described above inherit from the BasicRaster class which inherits from BasicRaster. The BasicRaster class describes the main properties of a raster such as the number of columns and rows, and it contains an object of the link[raster]{Extent-class} to describe its spatial extent (coordinates). It also holds the 'coordinate reference system' in a slot of class CRS-class defined in the sp package. A BasicRaster cannot contain any raster cell values and is therefore seldomly used.

The Raster* class inherits from BasicRaster. It is a virtual class; which means that you cannot create an object of this class. It is used only to define methods for all the classes that inherit from it (RasterLayer, RasterStack and RasterBrick). Another virtual class is the RasterStackBrick class. It is formed by a class union of RasterStack and RasterBrick. You cannot make objects of it, but methods defined for objects of this class as arguments will accept objects of the RasterLayer and RasterStack as that argument.

Classes RasterLayer and RasterBrick have a slot with an object of class RasterFile that describes the properties of the file they point to (if they do). RasterLayer has a slot with an object of class SingleLayerData, and the RasterBrick class has a slot with an object of class MultipleLayerData. These 'datalayer' classes can contain (some of) the values of the raster cells.
These classes are not further described here because users should not need to directly access these slots. The ‘setter’ functions such as `setValues` should be used instead. Using such ‘setter’ functions is much safer because a change in one slot should often affect the values in other slots.

**Objects from the Class**

Objects can be created by calls of the form `new("RasterLayer", ...)`, or with the helper functions such as `raster`.

**Slots**

Slots for RasterLayer and RasterBrick objects

- title: Character
- file: Object of class ".RasterFile"
- data: Object of class ".SingleLayerData" or ".MultipleLayerData"
- history: To record processing history, not yet in use
- legend: Object of class ".RasterLegend", Default legend. Should store preferences for plotting. Not yet implemented except that it stores the color table of images, if available
- extent: Object of `Extent-class`
- ncols: Integer
- nrows: Integer
- crs: Object of class "CRS", i.e. the coordinate reference system. In Spatial* objects this slot is called 'proj4string''

**Examples**

```r
showClass("RasterLayer")
```

---

**rasterFromCells**

*Subset a raster by cell numbers*

**Description**

This function returns a new raster based on an existing raster and cell numbers for that raster. The new raster is cropped to the cell numbers provided, and, if `values=TRUE` has values that are the cell numbers of the original raster.

**Usage**

```r
rasterFromCells(x, cells, values=TRUE)
```
Arguments

- **x**: Raster* object (or a SpatialPixels* or SpatialGrid* object)
- **cells**: vector of cell numbers
- **values**: Logical. If TRUE, the new RasterLayer has cell values that correspond to the cell numbers of x

Details

Cell numbers start at 1 in the upper left corner, and increase from left to right, and then from top to bottom. The last cell number equals the number of cells of the Raster* object.

Value

RasterLayer

See Also

- `rowFromCell`

Examples

```r
r <- raster(ncols=100, nrows=100)
cells <- c(3:5, 210)
r <- rasterFromCells(r, cells)
cbind(1:ncell(r), getValues(r))
```

Description

Create a Raster* object from x, y and z values. x and y represent spatial coordinates and must be on a regular grid. If the resolution is not supplied, it is assumed to be the minimum distance between x and y coordinates, but a resolution of up to 10 times smaller is evaluated if a regular grid can otherwise not be created. z values can be single or multiple columns (variables) If the exact properties of the RasterLayer are known beforehand, it may be preferable to simply create a new RasterLayer with the raster function instead, compute cell numbers and assign the values with these (see example below).

Usage

```r
rasterFromXYZ(xyz, res=c(NA,NA), crs=NA, digits=5)
```
Arguments

- **xyz**: matrix or data.frame with at least three columns: x and y coordinates, and values (z). There may be several 'z' variables (columns)
- **res**: numeric. The x and y cell resolution (optional)
- **crs**: CRS object or a character string describing a projection and datum in PROJ.4 format
- **digits**: numeric, indicating the requested precision for detecting whether points are on a regular grid (a low number of digits is a low precision)

Value

RasterLayer or RasterBrick

See Also

See `rasterize` for points that are not on a regular grid

Examples

```r
r <- raster(nrow=10, ncol=10, xmn=0, xmx=10, ymn=0, ymx=10, crs=NA)
r[] <- runif(ncell(r))
r[r<0.5] <- NA
xyz <- rasterToPoints(r)

r2 <- rasterFromXYZ(xyz)
# equivalent to:
r3 <- raster(nrow=10, ncol=10, xmn=0, xmx=10, ymn=0, ymx=10)
cells <- cellFromXY(r3, xyz[,1:2])
r3[cells] <- xyz[,3]
```

---

**rasterize**  
*Rasterize points, lines, or polygons*

Description

Transfer values associated with 'object' type spatial data (points, lines, polygons) to raster cells.

For polygons, values are transferred if the polygon covers the center of a raster cell. For lines, values are transferred to all cells that are touched by a line. You can combine this behaviour by rasterizing polygons as lines first and then as polygons.

If x represents points, each point is assigned to a grid cell. Points that fall on a border between cells are placed in the cell to the right and/or in the cell below. The value of a grid cell is determined by the values associated with the points and function fun.
rasterize

Usage

## S4 method for signature 'matrix,Raster'
rasterize(x, y, fun='last', background=NA,
           mask=FALSE, update=FALSE, updateValue='all', filename="", na.rm=TRUE, ...)

## S4 method for signature 'SpatialPoints,Raster'
rasterize(x, y, fun='last', background=NA,
           mask=FALSE, update=FALSE, updateValue='all', filename="", na.rm=TRUE, ...)

## S4 method for signature 'SpatialLines,Raster'
rasterize(x, y, fun='last', background=NA,
           mask=FALSE, update=FALSE, updateValue='all', filename="", ...)

## S4 method for signature 'SpatialPolygons,Raster'
rasterize(x, y, fun='last', background=NA,
           mask=FALSE, update=FALSE, updateValue='all', filename="", update=FALSE, updateValue='all', ...)

Arguments

x points (a SpatialPoints* object, or a two-column matrix (or data.frame)), SpatialLines*, SpatialPolygons*, or an Extent object

y Raster* object

field numeric or character. The value(s) to be transferred. This can be a single number, or a vector of numbers that has the same length as the number of spatial features (points, lines, polygons). If x is a Spatial*DataFrame, this can be the column name of the variable to be transferred. If missing, the attribute index is used (i.e. numbers from 1 to the number of features). You can also provide a vector with the same length as the number of spatial features, or a matrix where the number of rows matches the number of spatial features

fun function or character. To determine what values to assign to cells that are covered by multiple spatial features. You can use functions such as min, max, or mean, or one of the following character values: 'first', 'last', 'count'. The default value is 'last'. In the case of SpatialLines*, 'length' is also allowed (currently for planar coordinate systems only).

If x represents points, fun must accept a na.rm argument, either explicitly or through 'dots'. This means that fun=length fails, but function(x,...)length(x) works, although it ignores the na.rm argument. To use the na.rm argument you can use a function like this: fun=function(x, na.rm)if (na.rm) length(na.omit(x)) else (length(x), or use a function that removes NA values in all cases, like this function to compute the number of unique values "richness": fun=function(x, ...) {length(unique(x, na.rm=TRUE))}

If you want to know the number of points in each grid cell, you can use fun='count' or fun=function(x,...){length(x)}. For the number of unique values per grid cell you can use: fun=function(x, ...) { length(unique(na.rm(x)))}. You can also pass multiple functions using a statement like fun=function(x, ...) c(length(x),mean(x)), in which case the returned object is a RasterBrick (multiple layers).
background numeric. Value to put in the cells that are not covered by any of the features of x. Default is NA

mask logical. If TRUE the values of the input Raster object are 'masked' by the spatial features of x. That is, cells that spatially overlap with the spatial features retain their values, the other cells become NA. Default is FALSE. This option cannot be used when update=TRUE

update logical. If TRUE, the values of the Raster* object are updated for the cells that overlap the spatial features of x. Default is FALSE. Cannot be used when mask=TRUE

updateValue numeric (normally an integer), or character. Only relevant when update=TRUE. Select, by their values, the cells to be updated with the values of the spatial features. Valid character values are 'all', 'NA', and '!NA'. Default is 'all'

filename character. Output filename (optional)

na.rm If TRUE, NA values are removed if fun honors the na.rm argument

getCover logical. If TRUE, the fraction of each grid cell that is covered by the polygons is returned (and the values of field, fun, mask, and update are ignored. The fraction covered is estimated by dividing each cell into 100 subcells and determining presence/absence of the polygon in the center of each subcell

silent Logical. If TRUE, feedback on the polygon count is suppressed. Default is FALSE

... Additional arguments for file writing as for writeRaster

Value

RasterLayer or RasterBrick

See Also

extract

Examples

# rasterize points
r <- raster(ncols=36, nrows=18)
n <- 1000
x <- runif(n) * 360 - 180
y <- runif(n) * 180 - 90
xy <- cbind(x, y)
# get the (last) indices
r0 <- rasterize(xy, r)
# presence/absence (NA) (is there a point or not?)
r1 <- rasterize(xy, r, field=1)
# how many points?
r2 <- rasterize(xy, r, fun=function(x,...)length(x))
vals <- runif(n)
# sum of the values associated with the points
r3 <- rasterize(xy, r, vals, fun=sum)

# with a SpatialPointsDataFrame
vals <- 1:n
p <- data.frame(xy, name=vals)
coordinates(p) <- ~x+y
r <- rasterize(p, r, 'name', fun=min)
#r2 <- rasterize(p, r, 'name', fun=max)
#plot(r, r2, cex=0.5)

rasterize lines

cds1 <- rbind(c(-180,-20), c(-140,55), c(10, 0), c(-140,-60))
cds2 <- rbind(c(-10,0), c(140,60), c(160,0), c(140,-55))
cds3 <- rbind(c(-125,0), c(0,60), c(40.5, c(15,-45))

lines <- spLines(cds1, cds2, cds3)

r <- raster(ncols=90, nrows=45)
r <- rasterize(lines, r)

# Not run:
plot(r)
plot(lines, add=TRUE)

r <- rasterize(lines, r, fun='count')
plot(r)

plot(r)
plot(pols, add=T)
```

```r
# add a polygon
p5 <- rbind(c(-180,10), c(0,90), c(40,90), c(145,-10), c(-25, -15), c(-180,8), c(-180,10))
addpoly <- SpatialPolygons(list(Polygons(list(Polygon(p5)), 1)))
addpoly <- as(addpoly, "SpatialPolygonsDataFrame")
addpoly@data[1,1] <- 10
r2 <- rasterize(addpoly, r, field=1, update=TRUE, updateValue="NA")
plot(r2)
plot(pols, border="blue", lwd=2, add=TRUE)
plot(addpoly, add=TRUE, border="red", lwd=2)
```

```r
# get the percentage cover of polygons in a cell
r3 <- raster(ncol=36, nrow=18)
r3 <- rasterize(pols, r3, getCover=TRUE)
```

## End(Not run)

---

### rasterTmpFile

**Temporary files**

### Description

Functions in the raster package create temporary files if the values of an output RasterLayer cannot be stored in memory (RAM). This can happen when no filename is provided to a function and in functions where you cannot provide a filename (e.g. when using `raster algebra`).

Temporary files are automatically removed at the start of each session. During a session you can use `showTmpFiles` to see what is there and `removeTmpFiles` to delete all the temporary files. `rasterTmpFile` returns a temporary filename. These can be useful when developing your own functions. These filenames consist of `prefix_date_time_pid` where `pid` is the process id returned by `Sys.getpid` and `rn` is a 5 digit random number. This should make tempfiles unique if created at different times and also when created in parallel processes (different pid) that use `set.seed` and call `rasterTmpFile` at the same time. It is possible, however, to create overlapping names (see the examples), which is undesirable and can be avoided by setting the prefix argument.

### Usage

```r
rasterTmpFile(prefix='r_tmp_')
showTmpFiles()
removeTmpFiles(h=24)
```
rasterToContour

Arguments

prefix    Character. Prefix to the filename (which will be followed by 10 random numbers)
h        Numeric. The minimum age of the files in number of hours (younger files are not deleted)

Details

The default path where the temporary files are stored is returned (can be changed with rasterOptions).

Value

rasterTmpFile returns a valid file name
showTmpFiles returns the names (.grd only) of the files in the temp directory
removeTmpFiles returns nothing

See Also

rasterOptions, tempfile

Examples

## Not run:
rasterTmpFile('mytemp_')
showTmpFiles()
removeTmpFiles(h=24)

# It is possible (but undesirable!) to create overlapping temp file names.
for (i in 1:10) {
  set.seed(0)
  print(rasterTmpFile())
}
That can be avoided by using a prefix
for (i in 1:10) {
  set.seed(0)
  print(rasterTmpFile(prefix=paste('i', i, '_', sep='')))}

## End(Not run)

rasterToContour    Raster to contour lines conversion

Description

RasterLayer to contour lines. This is a wrapper around contourLines
Usage

rasterToContour(x, maxpixels=100000, ...)

Arguments

x            a RasterLayer object
maxpixels    Maximum number of raster cells to use; this function fails when too many cells
             are used
...          Any argument that can be passed to contourLines

Details

Most of the code was taken from maptools::ContourLines2SLDF, by Roger Bivand & Edzer Pebesma

Value

SpatialLinesDataFrame

Examples

f <- system.file("external/test.grd", package="raster")
r <- raster(f)
x <- rasterToContour(r)
class(x)
plot(r)
plot(x, add=TRUE)

rasterToPoints                  Raster to points conversion

Description

Raster to point conversion. Cells with NA are not converted. A function can be used to select a
subset of the raster cells (by their values).

Usage

rasterToPoints(x, fun=NULL, spatial=FALSE, ...)

Arguments

x            A Raster* object
fun          Function to select a subset of raster values
spatial      Logical. If TRUE, the function returns a SpatialPointsDataFrame object
...          Additional arguments. Currently only progress to specify a progress bar. "text",
             "window", or "" (the default, no progress bar)
**rasterToPolygons**

**Raster to polygons conversion**

**Description**

Raster to polygons conversion. Cells with NA are not converted. A function can be used to select a subset of the raster cells (by their values).

**Usage**

```
rasterToPolygons(x, fun=NULL, n=4, na.rm=TRUE, digits=12, dissolve=FALSE)
```

**Arguments**

- `x` Raster* object
- `fun` function to select a subset of raster values (only allowed if `x` has a single layer)
- `n` integer. The number of nodes for each polygon. Only 4, 8, and 16 are allowed
- `na.rm` If TRUE, cells with NA values in all layers are ignored
- `digits` number of digits to round the coordinates to
- `dissolve` logical. If TRUE, polygons with the same attribute value will be dissolved into multi-polygon regions. This option requires the rgeos package

**Details**

fun should be a simple function returning a logical value.
E.g.: `fun=function(x){x==1}` or `fun=function(x){x>3}`

**Examples**

```
r <- raster(nrow=18, ncol=36)
r[] <- runif(ncell(r)) * 10
r[r>8] <- NA
p <- rasterToPoints(r)
p <- rasterToPoints(r, fun=function(x){x>6})
#plot(r)
#points(p)
```

**Details**

fun should be a simple function returning a logical value.
E.g.: `fun=function(x){x==1}` or `fun=function(x){x>3 & x<6}`

**Value**

A matrix with three columns: x, y, and v (value), or a SpatialPointsDataFrame object.
Value

SpatialPolygonsDataFrame

Examples

```r
r <- raster(nrow=18, ncol=36)
r[] <- runif(ncell(r)) * 10
r[r>8] <- NA
pol <- rasterToPolygons(r, fun=function(x)(x>6))

#plot(r > 6)
#plot(pol, add=TRUE, col='red')
```

---

**readAll**

*Read values from disk*

**Description**

Read all values from a raster file associated with a Raster* object into memory. This function should normally not be used. In most cases `getValues` or `getValuesBlock` is more appropriate as `readAll` will fail when there is no file associated with the RasterLayer (values may only exist in memory).

**Usage**

```r
readAll(object)
```

**Arguments**

- `object` a Raster* object

**See Also**

`getValues`, `getValuesBlock`, `extract`

**Examples**

```r
r <- raster(system.file("external/test.grd", package="raster"))
r <- readAll(r)
```
Description

Reclassify values of a Raster* object. The function (re)classifies groups of values to other values. For example, all values between 1 and 10 become 1, and all values between 11 and 15 become 2 (see functions subs and cut for alternative approaches).

Reclassification is done with matrix rcl, in the row order of the reclassify table. Thus, if there are overlapping ranges, the first time a number is within a range determines the reclassification value.

Usage

```r
## S4 method for signature 'Raster'
reclassify(x, rcl, filename='', include.lowest=FALSE, right=TRUE, ...)
```

Arguments

- **x**: Raster* object
- **rcl**: matrix for reclassification. This matrix must have 3 columns. The first two columns are "from" "to" of the input values, and the third column "becomes" has the new value for that range. (You can also supply a vector that can be coerced into a n*3 matrix (with byrow=TRUE)). You can also provide a two column matrix ("is", "becomes") which can be useful for integer values. In that case, the right argument is automatically set to NA.
- **filename**: character. Output filename (optional)
- **include.lowest**: logical, indicating if a value equal to the lowest value in rcl (or highest value in the second column, for right = FALSE) should be included. The default is FALSE.
- **right**: logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa. The default is TRUE. A special case is to use right=NA. In this case both the left and right intervals are open.
- **...**: additional arguments as for writeRaster

Value

- Raster* object

See Also

- subs, cut, calc
Examples

```r
r <- raster(ncols=36, nrows=18)
r[] <- runif(ncell(r))
# reclassify the values into three groups
# all values >= 0 and <= 0.25 become 1, etc.
m <- c(0, 0.25, 1, 0.25, 0.5, 2, 0.5, 1, 3)
rclmat <- matrix(m, ncol=3, byrow=TRUE)
rc <- reclassify(r, rclmat)

# equivalent to
rc <- reclassify(r, c(-Inf,0.25,1, 0.25,0.5,2, 0.5,Inf,3))
```

---

**rectify**  
**rectify a Raster object**

Description

rectify changes a rotated Raster* object into a non-rotated (rectangular) object. This is wrapper function around `resample`.

Usage

```r
rectify(x, ext, res, method='ngb', filename='', ...)```

Arguments

- `x` Raster* object to be rectified  
- `ext` Optional. Extent object or object from which an Extent object can be extracted  
- `res` Optional. Single or two numbers to set the resolution  
- `method` Method used to compute values for the new RasterLayer, should be "bilinear" for bilinear interpolation, or "ngb" for nearest neighbor  
- `filename` Character. Output filename  
- `...` Additional arguments as for `writeRaster`

Value

RasterLayer or RasterBrick object
replacement  

Replace cell values or layers of a Raster* object

Description

You can set values of a Raster* object, when \( i \) is a vector of cell numbers, a Raster*, Extent, or Spatial* object.

These are shorthand methods that work best for relatively small Raster* objects. In other cases you can use functions such as `calc` and `rasterize`.

Methods

\[
x[i] \leftarrow \text{value} \\
x[i,j] \leftarrow \text{value}
\]

Arguments:

- `x`: a Raster* object
- `i`: cell number(s), row number(s), Extent, Spatial* object
- `j`: columns number(s) (only available if `i` is (are) a row number(s))
- `value`: new cell value(s)

See Also

`calc`, `rasterize`

Examples

```r
r <- raster(ncol=10, nrow=5)
r[] <- 1:ncell(r) * 2
r[1,] <- 1
r[,1] <- 2
r[1,1] <- 3

s <- stack(r, sqrt(r))
s[s<5] <- NA
```

resample  

Resample a Raster object

Description

Resample transfers values between non matching Raster* objects (in terms of origin and resolution). Use `projectRaster` if the target has a different coordinate reference system (projection).

Before using resample, you may want to consider using these other functions instead: `aggregate`, `disaggregate`, `crop`, `extend`, `merge`. 
## Usage

```r
## S4 method for signature 'Raster,Raster'
resample(x, y, method="bilinear", filename="", ...)```

### Arguments

- `x`: Raster* object to be resampled
- `y`: Raster* object with parameters that `x` should be resampled to
- `method`: method used to compute values for the new RasterLayer, should be "bilinear" for bilinear interpolation, or "ngb" for using the nearest neighbor
- `filename`: character. Output filename (optional)
- `...`: Additional arguments as for `writeRaster`

### Value

RasterLayer or RasterBrick object

### Author(s)

Robert J. Hijmans and Joe Cheng

### See Also

- `aggregate`, `disaggregate`, `crop`, `extend`, `merge`, `projectRaster`

### Examples

```r
r <- raster(nrow=3, ncol=3)
r[] <- 1:ncell(r)
s <- raster(nrow=10, ncol=10)
s <- resample(r, s, method="bilinear")
#par(mfrow=c(1,2))
#plot(r)
#plot(s)
```

### Description

Get (or set) the x and/or y resolution of a Raster* object

## Usage

```r
xres(x)
yres(x)
res(x)
res(x) <- value
```
**RGB**  

Create a Red-Green-Blue Raster object

**Description**

Make a Red-Green-Blue object that can be used to create images.

**Usage**

```r
## S4 method for signature 'RasterLayer'
RGB(x, filename='', col=rainbow(25), breaks=NULL, alpha=FALSE, colNA='white', zlim=NULL, zlimcol=NULL, ext=NULL, ...)
```

**Arguments**

- `x`: RasterBrick or RasterStack
- `filename`: character. Output filename (optional)
- `col`: A color palette, that is a vector of n contiguous colors generated by functions like `rainbow`, `heat.colors`, `topo.colors`, `bpy.colors` or one or your own making, perhaps using `colorRampPalette`. If none is provided, `rev(terrain.colors(255))` is used unless `x` has a `color table`
breaks numeric. A set of finite numeric breakpoints for the colours: must have one more breakpoint than colour and be in increasing order
alpha If TRUE a fourth layer to set the background transparency is added
colNA color for the background (NA values)
zlim vector of length 2. Range of values to plot
zlimcol If NULL the values outside the range of zlim get the color of the extremes of the range. If zlimcol has any other value, the values outside the zlim range get the color of NA values (see colNA)
ext An Extent object to zoom in to a region of interest (see drawExtent)
... additional arguments as for writeRaster

See Also
plotRGB

Examples
r <- raster(system.file("external/test.grd", package="raster"))
x <- RGB(r)
plot(x, col=gray(0:9/10))
plotRGB(x)

---

**Description**

Rotate a Raster* object that has x coordinates (longitude) from 0 to 360, to standard coordinates between -180 and 180 degrees. Longitude between 0 and 360 is frequently used in global climate models.

**Usage**

```r
## S4 method for signature 'Raster'
rotate(x, filename='', ...)"
See Also

flip

Examples

r <- raster(nrow=18, ncol=36)
m <- matrix(1:ncell(r), nrow=18)
r[] <- as.vector(t(m))
extent(r) <- extent(0, 360, -90, 90)
rr <- rotate(r)

rotated Do the raster cells have a rotation?

Description

Do the raster cells have a rotation?

Usage

rotated(x)

Arguments

x A Raster* object

Value

Logical value

See Also

rectify

Examples

r <- raster()
rotated(r)
Description

These functions take a single RasterLayer argument \( x \) and change its values to integers.

\texttt{ceiling} returns a RasterLayer with the smallest integers not less than the corresponding values of \( x \).
\texttt{floor} returns a RasterLayer with the largest integers not greater than the corresponding values of \( x \).
\texttt{trunc} returns a RasterLayer with the integers formed by truncating the values in \( x \) toward 0.
\texttt{round} returns a RasterLayer with values rounded to the specified number of digits (decimal places; default 0).

Details

see \texttt{?base::round}

Value

a RasterLayer object

Methods

\texttt{ceiling(x) floor(x) trunc(x, \ldots) round(x, digits = 0)}

a RasterLayer object

digits integer indicating the precision to be used

\ldots additional arguments

See Also

\texttt{round}

Examples

\begin{verbatim}
  r <- raster(ncol=10, nrow=10)
  r[] <- runif(ncell(r)) * 10
  s <- round(r)
\end{verbatim}
rowFromCell

Row or column number from a cell number

Description

These functions get the row and/or column number from a cell number of a Raster* object.

Usage

\[
\begin{align*}
\text{colFromCell}(\text{object}, \text{cell}) \\
\text{rowFromCell}(\text{object}, \text{cell}) \\
\text{rowColFromCell}(\text{object}, \text{cell})
\end{align*}
\]

Arguments

- **object**: Raster* object (or a SpatialPixels* or SpatialGrid* object)
- **cell**: cell number(s)

Details

The colFromCell and similar functions accept a single value, or a vector or list of these values. Cell numbers start at 1 in the upper left corner, and increase from left to right, and then from top to bottom. The last cell number equals the number of cells of the Raster* object.

Value

row of column number(s)

See Also

- `cellFrom`

Examples

\[
\begin{align*}
r & \leftarrow \text{raster}(\text{ncols}=10, \text{nrows}=10) \\
\text{colFromCell}(r, \text{c}(5, 15)) \\
\text{rowFromCell}(r, \text{c}(5, 15)) \\
\text{rowColFromCell}(r, \text{c}(5, 15))
\end{align*}
\]
rowSums

rowSums and colSums for Raster objects

Description

Sum values of Raster objects by row or column.

Usage

```r
\# S4 method for signature 'Raster'
rowSums(x, na.rm=FALSE, dims=1L,...)
\# S4 method for signature 'Raster'
colSums(x, na.rm=FALSE, dims=1L,...)
```

Arguments

- `x` Raster* object
- `na.rm` logical. If TRUE, NA values are ignored
- `dims` this argument is ignored
- `...` additional arguments (none implemented)

Value

vector (if `x` is a RasterLayer) or matrix

See Also

See `cellStats` for summing all cells values

Examples

```r
r <- raster(ncols=2, nrows=5)
values(r) <- 1:10
as.matrix(r)
rowSums(r)
colSums(r)
```
SampleInt  

Sample integer values

Description

Take a random sample from a range of integer values between 1 and n. Its purpose is similar to that of `sample`, but that function fails when n is very large.

Usage

```r
sampleInt(n, size, replace=FALSE)
```

Arguments

- **n**  
  Positive number (integer); the number of items to choose from

- **size**  
  Non-negative integer; the number of items to choose

- **replace**  
  Logical. Should sampling be with replacement?

Value

vector of integer numbers

Examples

```r
sampleInt(1e+12, 10)
```

# this may fail:
# sample.int(1e+12, 10)
# sample.int(1e+9, 10)

sampleRandom  

Random sample

Description

Take a random sample from the cell values of a Raster* object (without replacement).

Usage

```r
## S4 method for signature 'Raster'
sampleRandom(x, size, na.rm=TRUE, ext=NULL,
              cells=FALSE, rowcol=FALSE, xy=FALSE, sp=FALSE, asRaster=FALSE, ...)
```
Arguments

x Raster* object
size positive integer giving the number of items to choose
na.rm logical. If TRUE (the default), NA values are removed from random sample
ext Extent object. To limit regular sampling to the area within the extent
cells logical. If TRUE, sampled cell numbers are also returned
rowcol logical. If TRUE, sampled row and column numbers are also returned
xy logical. If TRUE, coordinates of sampled cells are also returned
sp logical. If TRUE, a SpatialPointsDataFrame is returned
asRaster logical. If TRUE, a Raster* object is returned with random cells with values, all other cells with NA
... Additional arguments as in writeRaster. Only relevant when asRaster=TRUE

Details

With argument na.rm=TRUE, the returned sample may be smaller than requested

Value

A vector, matrix (if cells=TRUE or x is a multi-layered object), or a SpatialPointsDataFrame (if sp=TRUE )

See Also

sampleRegular, sampleStratified

Examples

r <- raster(system.file("external/test.grd", package="raster"))
sampleRandom(r, size=10)
s <- stack(r, r)
sampleRandom(s, size=5, cells=TRUE, sp=TRUE)

Description

Take a systematic sample from a Raster* object.

Usage

## S4 method for signature 'Raster'
sampleRegular(x, size, ext=NULL, cells=FALSE, xy=FALSE, asRaster=FALSE, sp=FALSE, useGDAL=FALSE, ...)
sampleStratified

Arguments

- **x**: Raster object
- **size**: positive integer giving the number of items to choose.
- **ext**: Extent. To limit regular sampling to the area within that box
- **cells**: logical. Also return sampled cell numbers (if asRaster=FALSE)
- **xy**: logical. If TRUE, coordinates of sampled cells are also returned
- **asRaster**: logical. If TRUE, a RasterLayer or RasterBrick is returned, rather then the sampled values
- **sp**: logical. If TRUE, a SpatialPointsDataFrame is returned
- **useGDAL**: logical. If TRUE, GDAL is used to sample in some cases. This is quicker, but can result in values for a different set of cells than when useGDAL=FALSE. Only for rasters that are accessed via rgdal, and are not rotated. When TRUE arguments cells, xy, and sp are ignored (i.e., FALSE
- **...**: additional arguments. None implemented

Value

A vector (single layer object), matrix (multi-layered object; or if cells=TRUE, or xy=TRUE), Raster* object (if asRaster=TRUE), or SpatialPointsDataFrame (if sp=TRUE)

See Also

sampleRandom, sampleStratified

Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
v <- sampleRegular(r, size=100)
x <- sampleRegular(r, size=100, asRaster=TRUE)
```

---

sampleStratified  Stratified random sample

Description

Take a stratified random sample from the cell values of a Raster* object (without replacement). An attempt is made to sample size cells from each stratum. The values in the RasterLayer x are rounded to integers; with each value representing a stratum.

Usage

```r
## S4 method for signature 'RasterLayer'
sampleStratified(x, size, exp=10, na.rm=TRUE, xy=FALSE, ext=NULL, sp=FALSE, ...)
```
Arguments

- **x**: Raster object, with values (rounded to integers) representing strata
- **size**: positive integer giving the number of items to choose
- **exp**: numeric >= 1. 'Expansion factor' that is multiplied with size to get an initial sample. Can be increased when you get an insufficient number of samples for small strata
- **na.rm**: logical. If TRUE (the default), NA values are removed from random sample
- **xy**: logical. Return coordinates of cells rather than cell numbers
- **ext**: Extent object. To limit regular sampling to the area within the extent
- **sp**: logical. If TRUE, a SpatialPointsDataFrame is returned
- **...**: Additional arguments. None implemented

Details

The function may not work well when the size (number of cells) of some strata is relatively small.

Value

matrix of cell numbers (and optionally coordinates) by stratum

See Also

`sampleRandom`, `sampleRegular`

Examples

```r
r <- raster(ncol=10, nrow=10)
names(r) <- 'stratum'
r[] <- round((runif(ncell(r))+0.5)*3)
sampleStratified(r, size=3)
```

---

**scale**

*Scale values*

Description

Center and/or scale raster data

Usage

```r
## S4 method for signature 'Raster'
scale(x, center=TRUE, scale=TRUE)
```
Add a scalebar to a plot

Usage

scalebar(d, xy = NULL, type = "line", divs = 2, below = "", lonlat = NULL, label, adj=c(0.5, -0.5), lwd = 2, ...)

Arguments

distance covered by scalebar

x and y coordinate to place the plot. Can be NULL. Use xy=click() to make this interactive

"line" or "bar"

Number of divisions for a bar type. 2 or 4

Text to go below scalebar (e.g., "kilometers")
select

lonlat Logical or NULL. If logical, TRUE indicates if the plot is using longitude/latitude coordinates. If NULL this is guessed from the plot’s coordinates

adj adjustment for text placement

label Vector of three numbers to label the scale bar (beginning, midpoint, end)

lwd line width for the "line" type scalebar

... arguments to be passed to other methods

Value

None. Use for side effect of a scalebar added to a plot

Author(s)

Robert J. Hijmans; partly based on a function by Josh Gray

See Also

plot

Examples

f <- system.file("external/test.grd", package="raster")
r <- raster(f)
plot(r)
scalebar(1000)
scalebar(1000, xy=c(178000, 333500), type='bar', divs=4)

select Geometric subsetting

Description

Geometrically subset Raster* or Spatial* objects by drawing on a plot (map).

Usage

## S4 method for signature 'Raster'
select(x, use='rec', ...)

## S4 method for signature 'Spatial'
select(x, use='rec', draw=TRUE, col='cyan', size=2, ...)
select

Arguments

- **x**: Raster*, SpatialPoints*, SpatialLines*, or SpatialPolygons*
- **use**: character: 'rec' or 'pol'. To use a rectangle or a polygon for selecting
- **draw**: logical. Add the selected features to the plot?
- **col**: color to use to draw the selected features (when draw=TRUE)
- **size**: integer > 0. Size to draw the selected features with (when draw=TRUE))
- **...**: additional arguments. None implemented

Value

- Raster* or Spatial* object

See Also

- click, crop

Examples

```r
## Not run:

# select a subset of a RasterLayer
r <- raster(nrow=10, ncol=10)
r[] <- 1:ncell(r)
plot(r)
s <- select(r) # now click on the map twice

# plot the selection on a new canvas:
x11()
plot(s)

# select a subset of a SpatialPolygons object
p1 <- rbind(c(-180,-20), c(-140,55), c(10, 0), c(-140,-60), c(-180,-20))
hole <- rbind(c(-150,-20), c(-100,-10), c(-110,20), c(-150,-20))
p2 <- rbind(c(-10,0), c(140,60), c(160,0), c(140,-55), c(-10,0))
p3 <- rbind(c(-125,0), c(0,50), c(40,5), c(15,-45), c(-125,0))
pols <- SpatialPolygons( list( Polygons(list(Polygon(p1), Polygon(hole))), 1),
                         Polygons(list(Polygon(p2)), 2), Polygons(list(Polygon(p3)), 3))
pols@polygons[[1]]@Polygons[[2]]@hole <- TRUE

plot(pols, col=rainbow(3))
s <- select(pols) # now click on the map twice
ps

## End(Not run)
```
setExtent

Set the extent of a RasterLayer

Description

setExtent sets the extent of a Raster* object. Either by providing a new Extent object or by setting the extreme coordinates one by one.

Usage

setExtent(x, ext, keepres=FALSE, snap=FALSE)
extent(x) <- value

Arguments

x A Raster* object
ext An object of class Extent (which you can create with extent, or an object that has an extent (e.g. a Raster* or Spatial* object) )
keepres logical. If TRUE, the resolution of the cells will stay the same after adjusting the bounding box (by adjusting the number of rows and columns). If FALSE, the number of rows and columns will stay the same, and the resolution will be adjusted.
snap logical. If TRUE, the extent is adjusted so that the cells of the input and output RasterLayer are aligned
value An object of class Extent (which you can create with extent )

Value

A Raster* object

See Also

extent, Extent-class

Examples

r <- raster()
bb <- extent(-10, 10, -20, 20)
extent(r) <- bb
r <- setExtent(r, bb, keepres=TRUE)
**setMinMax**

*Compute min and max values*

**Description**

The minimum and maximum value of a RasterLayer are computed (from a file on disk if necessary) and stored in the returned Raster* object.

**Usage**

```r
setMinMax(x)
```

**Arguments**

- `x` : A Raster* object

**Value**

- a Raster* object

**See Also**

`getValues`

**Examples**

```r
r <- raster(system.file("external/test.grd", package="raster"))
r
r <- setMinMax(r)
r
```

---

**setValues**

*Set values of a Raster object*

**Description**

You can use the `setValues` function to assign values to a Raster* object. While you can access the `values` slot of the objects directly, you would do that at your own peril because when setting values, multiple slots need to be changed; which is what these functions do.
setValues

Usage

## S4 method for signature 'RasterLayer'
setValues(x, values, ...)

## S4 method for signature 'RasterBrick'
setValues(x, values, layer=1, ...)

## S4 method for signature 'RasterStack'
setValues(x, values, layer=1, ...)

## S4 method for signature 'RasterLayerSparse'
setValues(x, values, index=NULL, ...)

values(x) <- value

Arguments

- **x**: A Raster*
- **values**: Cell values to associate with the Raster* object. There should be values for all cells
- **value**: Cell values to associate with the Raster* object. There should be values for all cells
- **layer**: Layer number (only relevant for RasterBrick and RasterStack objects). If missing, the values of all layers is set
- **index**: Cell numbers corresponding to the values
- **...**: Additional arguments (none implemented)

Value

- a Raster* object

See Also

replacement

Examples

```r
r <- raster(ncol=10, nrow=10)
vals <- 1:ncell(r)
r <- setValues(r, vals)
# equivalent to
r[] <- vals
```
shapefile

Read or write a shapefile

Description

Reading and writing of "ESRI shapefile" format spatial data. Only the three vector types (points, lines, and polygons) can be stored in shapefiles. These are simple wrapper functions around readOGR and writeOGR (rgdal package). A shapefile should consist of at least four files: .shp (the geometry), .dbf (the attributes), .shx (the index that links the two, and .prj (the coordinate reference system). If the .prj file is missing, a warning is given. If any other file is missing an error occurs (although one could in principle recover the .shx from the .shp file). Additional files are ignored.

Usage

```r
## S4 method for signature 'character'
shapefile(x, stringsAsFactors=FALSE, verbose=FALSE, warnPRJ=TRUE, ...)
```

```r
## S4 method for signature 'Spatial'
shapefile(x, filename='', overwrite=FALSE, ...)```

Arguments

- `x` character (a file name, when reading a shapefile) or Spatial* object (when writing a shapefile)
- `filename` character. Filename to write a shapefile
- `overwrite` logical. Overwrite existing shapefile?
- `verbose` logical. If TRUE, information about the file is printed
- `warnPRJ` logical. If TRUE, a warning is given if there is no .prj file
- `stringsAsFactors` logical. If TRUE, strings are converted to factors
- `...` Additional arguments passed to rgdal functions readOGR or writeOGR

Value

Spatial*DataFrame (reading). Nothing is returned when writing a shapefile.

Examples

```r
if (require(rgdal)) {

filename <- system.file("external/lux.shp", package="raster")
filename
p <- shapefile(filename)
```

## Not run:
Description
Shift the location of a Raster* of vector type Spatial* object in the x and/or y direction

Usage
## S4 method for signature 'Raster'
shift(object, x=0, y=0, filename='', ...)  

## S4 method for signature 'SpatialPolygons'
shift(object, x=0, y=0, ...)  

## S4 method for signature 'SpatialLines'
shift(object, x=0, y=0, ...)  

## S4 method for signature 'SpatialPoints'
shift(object, x=0, y=0, ...)  

Arguments
- object: Raster* or Spatial* object
- x: numeric. The shift in horizontal direction
- y: numeric. The shift in vertical direction
- filename: character file name (optional)
- ...: if object is a Raster* object: additional arguments as for writeRaster

Value
Same object type as x

See Also
flip, rotate, and the elide function in the maptools package

Examples
```r
r <- raster()
r <- shift(r, x=1, y=-1)
```
Slope and aspect

Description

This is a deprecated function. Use `terrain` instead.

Usage

```r
slopeAspect(dem, filename='', out=c('slope', 'aspect'), unit='radians',
neighbors=8, flatAspect, ...)
```

Arguments

- `dem`: RasterLayer object with elevation values in map units, or in meters when the crs is longitude/latitude
- `filename`: Character. Filename. optional
- `out`: Character vector containing one or more of these options: 'slope', 'aspect'
- `unit`: Character. 'degrees' or 'radians'
- `neighbors`: Integer. Indicating how many neighboring cells to use to compute slope for any cell. Either 8 (queen case) or 4 (rook case), see Details
- `flatAspect`: Numeric or NA. What value to use for aspect when slope is zero (and hence the aspect is undefined)? The default value is 90 degrees (or 0.5*pi radians)
- `...`: Standard additional arguments for writing RasterLayer files

See Also

`terrain`

---

sp

Create SpatialLines* or SpatialPolygons*

Description

Helper functions to simplify the creation of SpatialLines* or SpatialPolygons* objects from coordinates.

Usage

```r
spLines(x, ..., attr=NULL, crs=NA)
spPolygons(x, ..., attr=NULL, crs=NA)
```
Arguments

- **x**: matrix of list with matrices. Each matrix must have two columns with x and y coordinates (or longitude and latitude, in that order). Multi-line or multi-polygon objects can be formed by combining matrices in a list
- **attr**: data.frame with the attributes to create a DataFrame object. The number of rows must match the number of lines/polygons
- **crs**: the coordinate reference system (PROJ4 notation)

Value

SpatialLines* or SpatialPolygons*

Examples

```r
x1 <- rbind(c(-180,-20), c(-140,55), c(10, 0), c(-140,-60))
x2 <- rbind(c(-10,0), c(140,60), c(160,0), c(140,-55))
x3 <- rbind(c(-125,0), c(0,60), c(40,5), c(15,-45))
x4 <- rbind(c(41,-41.5), c(51,-35), c(62,-41), c(51,-50))

a <- spLines(x1, x2, x3)
b <- spLines(x1, list(x2, x3), attr=data.frame(id=1:2), crs='+proj=longlat +datum=WGS84')

hole <- rbind(c(-150,-20), c(-100,-10), c(-110,20))
d <- spPolygons(list(x1,hole), x2, list(x3, x4))

att <- data.frame(ID=1:3, name=c('a', 'b', 'c'))
e <- spPolygons(list(x1,hole), x2, list(x3, x4), attr=att, crs='+proj=longlat +datum=WGS84')
```

spplot

Use spplot to plot a Raster* object

Description

A wrapper function around spplot (sp package). With spplot it is easy to map several layers with a single legend for all maps. spplot is itself a wrapper around the levelplot function in the lattice package, and see the help for these functions for additional options.

One of the advantages of these wrapper functions is the additional maxpixels argument to sample large Raster objects for faster drawing.
Methods

```
spplot(obj, ..., maxpixels=50000, as.table=TRUE)
```

- `obj`: A Raster* object
- `...`: Any argument that can be passed to `spplot` and `levelplot`
- `maxpixels`: Integer. Number of pixels to sample from each layer of large Raster objects

See Also

`plot`, `plotRGB`

The rasterVis package has more advanced plotting methods for Raster objects

Examples

```r
r <- raster(system.file("external/test.grd", package="raster"))
s <- stack(r, r*2)
names(s) <- c('meuse', 'meuse x 2')
spplot(s)

pts <- data.frame(sampleRandom(r, 10, xy=TRUE))
coordinates(pts) <- ~ x + y
spplot(s, scales = list(draw = TRUE),
xlab = "easting", ylab = "northing",
col.regions = rainbow(99, start=.1),
names.attr=c('original', 'times two'),
sp.layout = list("sp.points", pts, pch=20, cex=2, col='black'),
par.settings = list(fontsize = list(text = 12)), at = seq(0, 4000, 500))
```

---

**stack**

Create a RasterStack object

**Description**

A RasterStack is a collection of RasterLayer objects with the same spatial extent and resolution. A RasterStack can be created from RasterLayer objects, or from raster files, or both. It can also be created from a SpatialPixelsDataFrame or a SpatialGridDataFrame object.

**Usage**

```r
## S4 method for signature 'character'
stack(x, ..., bands=NULL, varname="", native=FALSE, RAT=TRUE, quick=FALSE)

## S4 method for signature 'Raster'
```
stack(x, ..., layers=NULL)

## S4 method for signature 'missing'
stack(x)

## S4 method for signature 'list'
stack(x, bands=NULL, native=FALSE, RAT=TRUE, ...)

**Arguments**

- `x` filename (character), Raster* object, missing (to create an empty RasterStack), SpatialGrid*, SpatialPixels*, or list (of filenames and/or Raster* objects). If `x` is a list, additional arguments ... are ignored.
- `bands` integer. which bands (layers) of the file should be used (default is all layers)
- `layers` integer (or character with layer names) indicating which layers of a RasterBrick should be used (default is all layers)
- `native` logical. If TRUE native drivers are used instead of gdal drivers (where available, such as for BIL and Arc-ASCII files)
- `RAT` logical. If TRUE a raster attribute table is created for files that have one
- `quick` logical. If TRUE the extent and resolution of the objects are not compared. This speeds up the creation of the RasteStack but should be use with great caution. Only use this option when you are absolutely sure that all the data in all the files are aligned, and you need to create RasterStack for many (>100) files
- `varname` character. To select the variable of interest in a NetCDF file (see raster
- ... additional filenames or Raster* objects

**Value**

RasterStack

**See Also**

`addLayer, dropLayer, raster, brick`

**Examples**

```r
# file with one layer
fn <- system.file("external/test.grd", package="raster")
s <- stack(fn, fn)
r <- raster(fn)
s <- stack(r, fn)
nlayers(s)

# file with three layers
slogo <- stack(system.file("external/rlogo.grd", package="raster"))
nlayers(slogo)
slogo
```
Apply a function on subsets of a RasterStack or RasterBrick

Description

Apply a function on subsets of a RasterStack or RasterBrick. The layers to be combined are indicated with the vector `indices`. The function used should return a single value, and the number of layers in the output Raster* equals the number of unique values in `indices`. For example, if you have a RasterStack with 6 layers, you can use `indices=c(1,1,2,2,2)` and `fun=sum`. This will return a RasterBrick with two layers. The first layer is the sum of the first three layers in the input RasterStack, and the second layer is the sum of the last three layers in the input RasterStack. Indices are recycled such that `indices=c(1,2)` would also return a RasterBrick with two layers (one based on the odd layers (1,3,5), the other based on the even layers (2,4,6)).

See `calc` if you want to use a more efficient function that returns multiple layers based on _all_ layers in the Raster* object.

Usage

```r
stackApply(x, indices, fun, filename='', na.rm=TRUE, ...)
```

Arguments

- `x`: Raster* object
- `indices`: integer. Vector of length `nLayers(x)` (shorter vectors are recycled) containing all integer values between 1 and the number of layers of the output Raster*
- `fun`: function that returns a single value, e.g. `mean` or `min`, and that takes a `na.rm` argument (or can pass through arguments via `...`)
- `na.rm`: logical. If `TRUE`, NA cells are removed from calculations
- `filename`: character. Optional output filename
- `...`: additional arguments as for `writeRaster`

Value

A new Raster* object, and in some cases the side effect of a new file on disk.

See Also

`calc`, `stackSelect`

Examples

```r
r <- raster(ncol=10, nrow=10)
r[] <- ncell(r)
s <- brick(r,r,r,r,r)
s <- s * 1:6
b1 <- stackApply(s, indices=c(1,1,1,2,2,2), fun=sum)
```
stackSave

Save or open a RasterStack file

Description

A RasterStack is a collection of RasterLayers with the same spatial extent and resolution. They can be created from RasterLayer objects, or from file names. These two functions allow you to save the references to raster files and recreate a rasterStack object later. They only work if the RasterStack points to layers that have their values on disk. The values are not saved, only the references to the files.

Usage

stackOpen(stackfile)
stackSave(x, filename)

Arguments

stackfile Filename for the RasterStack (to save it on disk)
x RasterStack object
filename File name

Details

When a RasterStack is saved to a file, only pointers (filenames) to raster datasets are saved, not the data. If the name or location of a raster file changes, the RasterStack becomes invalid.

Value

RasterStack object

See Also

writeRaster, stack, addLayer

Examples

file <- system.file("external/test.grd", package="raster")
s <- stack(c(file, file))
s <- stackSave(s, "mystack")
# note that filename adds an extension .stk to a stackfile
## Not run:
s2 <- stackOpen("mystack.stk")
s2

## End(Not run)
**stackSelect**

Select cell values from a multi-layer Raster* object

**Description**

Use a Raster* object to select cell values from different layers in a multi-layer Raster* object. The object to select values y should have cell values between 1 and nLayers(x). The values of y are rounded.

See `extract` for extraction of values by cell, point, or otherwise.

**Usage**

```r
## S4 method for signature 'RasterStack,Brick,Raster'
stackSelect(x, y, recycle=FALSE, type='index', filename='', ...)```

**Arguments**

- `x`: RasterStack or RasterBrick object
- `y`: Raster* object
- `recycle`: Logical. Recursively select values (default = FALSE. Only relevant if y has multiple layers. E.g. if x has 12 layers, and y has 4 layers, the indices of the y layers are used three times.
- `type`: Character. Only relevant when recycle=TRUE. Can be 'index' or 'truefalse'. If it is 'index', the cell values of y should represent layer numbers. If it is 'truefalse' layer numbers are indicated by 0 (not used, NA returned) and 1 (used)
- `filename`: Character. Output filename (optional)
- `...`: Additional arguments as for `writeRaster`

**Value**

Raster* object

**See Also**

`stackApply`, `extract`

**Examples**

```r
r <- raster(ncol=10, nrow=10)
r[] <- 1
s <- stack(r, r+2, r+5)
r[] <- round(runif(ncell(r)))*3
x <- stackSelect(s, r)
```
Description

Linear strech of values in a Raster object

Usage

stretch(x, minv=0, maxv=255, minq=0, maxq=1, filename='', ...)

Arguments

- x: Raster* object
- minv: numeric >= 0 and smaller than maxv. lower bound of streched value
- maxv: numeric <= 255 and larger than maxv. upper bound of streched value
- minq: numeric >= 0 and smaller than maxq. lower quitile bound of original value
- maxq: numeric <= 1 and larger than minq. upper quitile bound of original value
- filename: character. Filename for the output Raster object (optional)
- ...: additional arguments as for writeRaster

Value

Raster* object

See Also

stretch argument in plotRGB

Examples

r <- raster(nc=10, nr=10)
r[] <- 1:100 * 10
stretch(r)
s <- stack(r, r*2)
stretch(s)
subset

Subset layers in a Raster* object

Description

Extract a set of layers from a RasterStack or RasterBrick object.

Usage

```r
## S4 method for signature 'Raster'
subset(x, subset, drop=TRUE, filename='', ...)  
## S4 method for signature 'RasterStack'
subset(x, subset, drop=TRUE, filename='', ...)  
```

Arguments

- `x`: RasterBrick or RasterStack object
- `subset`: integer or character. Should indicate the layers (represented as integer or by their name)
- `drop`: If TRUE, a selection of a single layer will be returned as a RasterLayer
- `filename`: character. Output filename (optional)
- `...`: additional arguments as for `writeRaster`

Value

Raster* object

See Also

dropLayer

Examples

```r
s <- stack(system.file("external/rlogo.grd", package="raster"))
sel <- subset(s, 2:3)

# Note that this is equivalent to
sel2 <- s[[2:3]]

# and in this particular case:
sel3 <- dropLayer(s, 1)

nlayers(s)
nlayers(sel)
```
substitute

Substitute values in a Raster* object

Description

Substitute (replace) values in a Raster* object with values in a data.frame. The data.frame should have a column to identify the key (ID) to match with the cell values of the Raster* object, and one or more columns with replacement values. By default these are the first and second column but you can specify other columns with arguments by and which. It is possible to match one table to multiple layers, or to use multiple layers as a single key, but not both.

Usage

## S4 method for signature 'Raster,data.frame'
subs(x, y, by=1, which=2, subsWithNA=TRUE, filename='', ...)  

Arguments

x Raster* object
y data.frame
by column number(s) or name(s) identifying the key (ID) to match rows in data.frame y to values of the Raster object
which column number or name that has the new (replacement) values
subsWithNA logical. If TRUE values that are not matched become NA. If FALSE, they retain their original value (which could also be NA). This latter option is handy when you want to replace only one or a few values. It cannot be used when x has multiple layers
filename character. Optional output filename
... additional arguments as for writeRaster

Details

You could obtain the same result with reclassify, but subs is more efficient for simple replacement. Use reclassify if you want to replace ranges of values with new values.

You can also replace values using a fitted model. E.g. fit a model to glm or loess and then call predict

Value

Raster object
Description

Summarize a Raster* object. A sample is used for very large files.

Usage

## S4 method for signature 'RasterLayer'
summary(object, maxsamp=100000, ...)

Arguments

- **object**: Raster* object
- **maxsamp**: positive integer. Sample size used for large datasets
- **...**: additional arguments. None implemented

Value

matrix with (an estimate of) the median, minimum and maximum values, the first and third quartiles, and the number of cells with NA values

See Also

cellStats, link[raster]{quantile}
Summary methods

Description

The following summary methods are available for Raster* objects:

- mean, max, min, range, prod, sum, any, all

All methods take `na.rm` as an additional logical argument. Default is `na.rm=FALSE`. If TRUE, NA values are removed from calculations. These methods compute a summary statistic based on cell values of RasterLayers and the result of these methods is always a single RasterLayer (except for range, which returns a RasterBrick with two layers). See `calc` for functions not included here (e.g. median) or any other custom functions.

You can mix RasterLayer, RasterStack and RasterBrick objects with single numeric or logical values. However, because generic functions are used, the method applied is chosen based on the first argument: `x`. This means that if `r` is a RasterLayer object, `mean(r, 5)` will work, but `mean(5, r)` will not work.

To summarize all cells within a single RasterLayer, see `cellStats` and `maxValue` and `minValue`.

Value

- a RasterLayer

See Also

- `calc`

Examples

```r
r1 <- raster(nrow=10, ncol=10)
r1 <- setValues(r1, runif(ncell(r1)))
r2 <- setValues(r1, runif(ncell(r1)))
r3 <- setValues(r1, runif(ncell(r1)))
r <- max(r1, r2, r3)
r <- range(r1, r2, r3, 1.2)

s <- stack(r1, r2, r3)
r <- mean(s, 2)
```
**symdif**

**Symmetrical difference**

**Description**

Symmetrical difference of SpatialPolygons* objects

**Usage**

```r
## S4 method for signature 'SpatialPolygons,SpatialPolygons'
symdif(x, y, ...)  
```

**Arguments**

- `x`: SpatialPolygons* object
- `y`: SpatialPolygons* object
- `...`: Additional SpatialPolygons* object(s)

**Value**

SpatialPolygons*

**Author(s)**

Robert J. Hijmans

**See Also**

`erase`

**Examples**

```r
# SpatialPolygons
if (require(rgdal) & require(rgl)) {
  p <- shapefile(system.file("external/lux.shp", package="raster"))
  b <- as(extent(6, 6.4, 49.75, 50), 'SpatialPolygons')
  projection(b) <- projection(p)
  sd <- symdif(p, b)
  plot(sd, col='red')
}
```
terrain

Terrain characteristics

Description

Compute slope, aspect and other terrain characteristics from a raster with elevation data. The elevation data should be in map units (typically meter) for projected (planar) raster data. They should be in meters when the coordinate reference system (CRS) is longitude/latitude.

Usage

terrain(x, opt='slope', unit='radians', neighbors=8, filename='', ...)

Arguments

x RasterLayer object with elevation values. Values should have the same unit as the map units, or in meters when the crs is longitude/latitude

opt Character vector containing one or more of these options: slope, aspect, TPI, TRI, roughness, flowdir (see Details)

unit Character. 'degrees', 'radians' or 'tangent'. Only relevant for slope and aspect. If 'tangent' is selected that is used for slope, but for aspect 'degrees' is used (as 'tangent' has no meaning for aspect)

neighbors Integer. Indicating how many neighboring cells to use to compute slope for any cell. Either 8 (queen case) or 4 (rook case). Only used for slope and aspect, see Details

filename Character. Output filename (optional)

... Standard additional arguments for writing Raster* objects to file

Details

When neighbors=4, slope and aspect are computed according to Fleming and Hoffer (1979) and Ritter (1987). When neighbors=8, slope and aspect are computed according to Horn (1981). The Horn algorithm may be best for rough surfaces, and the Fleming and Hoffer algorithm may be better for smoother surfaces (Jones, 1997; Burrough and McDonnell, 1998). If slope = 0, aspect is set to 0.5*pi radians (or 90 degrees if unit='degrees'). When computing slope or aspect, the CRS (projection) of the RasterLayer x must be known (may not be NA), to be able to safely differentiate between planar and longitude/latitude data.

flowdir returns the 'flow direction' (of water), i.e. the direction of the greatest drop in elevation (or the smallest rise if all neighbors are higher). They are encoded as powers of 2 (0 to 7). The cell to the right of the focal cell 'x' is 1, the one below that is 2, and so on:

```
   32  64  128
   16   x   1
   8    4   2
```
If two cells have the same drop in elevation, a random cell is picked. That is not ideal as it may prevent the creation of connected flow networks. ArcGIS implements the approach of Greenlee (1987) and I might adopt that in the future.

The terrain indices are according to Wilson et al. (2007), as in gdaldem. TRI (Terrain Ruggedness Index) is the mean of the absolute differences between the value of a cell and the value of its 8 surrounding cells. TPI (Topographic Position Index) is the difference between the value of a cell and the mean value of its 8 surrounding cells. Roughness is the difference between the maximum and the minimum value of a cell and its 8 surrounding cells.

Such measures can also be computed with the focal function:

```r
f <- matrix(1, nrow=3, ncol=3)
TRI <- focal(x, w=f, fun=function(x, ...) sum(abs(x[-5]-x[5]))/8, pad=TRUE, padValue=NA)
TPI <- focal(x, w=f, fun=function(x, ...) x[5] - mean(x[-5]), pad=TRUE, padValue=NA)
rough <- focal(x, w=f, fun=function(x, ...) max(x) - min(x), pad=TRUE, padValue=NA, na.rm=TRUE)
```

**References**

**See Also**

hillShade

**Examples**

```r
# Not run:
elevation <- getData('alt', country='CHE')
x <- terrain(elevation, opt=c('slope', 'aspect'), unit='degrees')
plot(x)

# TPI for different neighborhood size:
tpiw <- function(x, w=5) {
```
m <- matrix(1/(w^2-1), nc=w, nr=w)
m[ceiling(0.5 * length(m))] <- 0
f <- focal(x, m)
x <- f
}
tpi5 <- tpiw(elevation, w=5)

## End(Not run)

---

**Add labels to a map**

**Description**

Plots labels, that is a textual (rather than color) representation of values, on top an existing plot (map).

**Usage**

```r
## S4 method for signature 'RasterLayer'
text(x, labels, digits=0, fun=NULL, halo=FALSE, ...)

## S4 method for signature 'RasterStackBrick'
text(x, labels, digits=0, fun=NULL, halo=FALSE, ...)

## S4 method for signature 'SpatialPolygons'
text(x, labels, halo=FALSE, ...)

## S4 method for signature 'SpatialPoints'
text(x, labels, halo=FALSE, ...)
```

**Arguments**

- `x`: Raster*, SpatialPoints* or SpatialPolygons* object
- `labels`: character. Optional. Vector of labels with length(x) or a variable name from names(x)
- `digits`: integer. how many digits should be used?
- `fun`: function to subset the values plotted (as in rasterToPoints)
- `halo`: logical. If TRUE a 'halo' is printed around the text. If TRUE, additional arguments hc='white' and hw=0.1 can be modified to set the colour and width of the halo
- `...`: additional arguments to pass to graphics function `text`

**See Also**

text, plot
### Examples

```r
r <- raster(nrows=4, ncols=4)
r <- setValues(r, 1:ncell(r))
plot(r)
text(r)

plot(r)
text(r, halo=TRUE, hc='blue', col='white', hw=0.2)

plot(r, col=bpy.colors(5))
text(r, fun=function(x){x<5 | x>12}, col=c('red', 'white'), vfont=c("sans serif", "bold"), cex=2)
```

---

### Description

Transpose a Raster* object

### Usage

```r
t(x)
```

### Arguments

- **x**: a Raster* object

### Value

RasterLayer or RasterBrick

### See Also

`transpose`, `flip`, `rotate`

### Examples

```r
r <- raster(nrow=18, ncol=36)
r[] <- 1:ncell(r)
rt <- t(r)
```
Description

Trim (shrink) a Raster* object by removing outer rows and columns that all have the same value (e.g. NA).

Or remove the whitespace before or after a string of characters (or a matrix, or the character values in a data.frame).

Usage

```r
## S4 method for signature 'Raster'
trim(x, padding=0, values=NA, filename='', ...)  
## S4 method for signature 'character'
trim(x, ...)
```

Arguments

- `x` Raster* object or a character string
- `values` numeric. Value(s) based on which a Raster* should be trimmed
- `padding` integer. Number of outer rows/columns to keep
- `filename` character. Optional output filename
- `...` If `x` is a Raster* object: additional arguments as for `writeRaster`

Value

A RasterLayer or RasterBrick object (if `x` is a Raster* object) or a character string (if `x` is a character string).

Author(s)

Robert J. Hijmans and Jacob van Etten

Examples

```r
r <- raster(ncol=18,nrow=18)
r[39:49] <- 1  
r[113:155] <- 2  
r[200] <- 6  
s <- trim(r)

trim("hi folks ! ")
```
union

Union Extent or SpatialPolygons* objects

Description

Extent objects: Objects are combined into their union. See crop and extend to union a Raster object with an Extent object.

Two SpatialPolygons* objects. Overlapping polygons (between layers, not within layers) are intersected, other spatial objects are appended. Tabular attributes are joined.

Single SpatialPolygons* object. Overlapping polygons are intersected. Original attributes are lost. New attributes allow for determining how many, and which, polygons overlapped.

Usage

```r
## S4 method for signature 'Extent,Extent'
union(x, y)

## S4 method for signature 'SpatialPolygons,SpatialPolygons'
union(x, y)

## S4 method for signature 'SpatialPolygons,missing'
union(x, y)
```

Arguments

- `x` Extent or SpatialPolygons* object
- `y` Same as `x` or missing

Value

Extent or SpatialPolygons object

See Also

intersect, extent, setExtent

merge for merging a data.frame with attributes of Spatial objects and +,SpatialPolygons,SpatialPolygons-method for an algebraic notation

Examples

```r
e1 <- extent(-10, 10, -20, 20)
e2 <- extent(0, 20, -40, 5)
union(e1, e2)

#SpatialPolygons
if (require(rgdal) & require(rgdal)) {
p <- shapefile(system.file("external/lux.shp", package="raster"))
```
unique

Unique values

Description

This function returns the unique values in a RasterLayer, or the unique combinations of values in a multi-layer raster object.

Usage

```r
## S4 method for signature 'RasterLayer,missing'
unique(x, incomparables=FALSE, ...)

## S4 method for signature 'RasterStackBrick,missing'
unique(x, incomparables=FALSE, ...)
```

Arguments

- `x` Raster object
- `incomparables` ignored. Must be missing
- `...` additional arguments. One implemented: `progress`, as in `writeRaster`

Value

vector or matrix

See Also

unique

Examples

```r
r <- raster(ncol=10, nrow=10)
r[] <- round(runif(ncell(r)) * 10)
unique(r)
unique(stack(r, round(r/2)))
```
unstack

Description

Create a list of RasterLayer objects from a RasterStack or RasterBrick

Usage

unstack(x, ...)

Arguments

x a RasterStack object

... not used. further arguments passed to or from other methods

Value

A list of RasterLayer objects

See Also

stack

Examples

file <- system.file("external/test.grd", package="raster")
s <- stack(file, file)
list1 <- unstack(s)
b <- brick(s)
list2 <- unstack(b)

update

Update raster cells of files (on disk)

Description

Update cell values of a file (i.e., cell values on disk) associated with a RasterLayer or RasterBrick. User beware: this function _will_ make changes to your file (first make a copy if you are not sure what you are doing).

Writing starts at a cell number cell. You can write a vector of values (in cell order), or a matrix. You can also provide a vector of cell numbers (of the same length as vector v) to update individual cells.

See writeFormats for supported formats.
Usage

update(object, ...)

Arguments

object RasterLayer or RasterBrick that is associated with a file

... Additional arguments.

v - vector or matrix with new values
cell - cell from where to start writing. Or a vector of cell numbers if v is a vector of the same length.
band - band (layer) to update (for RasterBrick objects).

Value

RasterLayer or RasterBrick

Examples

# setting up an example RasterLayer with file
r <- raster(nrow=5, ncol=10)
r[] = 0
r <- writeRaster(r, 'test', overwrite=TRUE, datatype='INT2S')
as.matrix(r)

# update with a vector starting a cell
r <- update(r, v=rep(1.5), cell=6)
# 99.99 gets rounded because this is an integer file
r <- update(r, v=9.99, cell=50)
as.matrix(r)

# update with a vector of values and matching vector of cell numbers
r <- update(r, v=5:1, cell=c(5,15,25,35,45))
as.matrix(r)

# updating with a matrix, anchored at a cell number
m = matrix(1:10, ncol=2)
r <- update(r, v=m, cell=2)
as.matrix(r)

validCell

Validity of a cell, column or row number

Description

Simple helper functions to determine if a row, column or cell number is valid for a certain Raster* object
validNames

Usage
validCell(object, cell)
validCol(object, colnr)
validRow(object, rownr)

Arguments
object Raster* object (or a SpatialPixels* or SpatialGrid* object)
       cell cell number(s)
       colnr column number; or vector of column numbers
       rownr row number; or vector of row numbers

Value
logical value

Examples
# using a new default raster (1 degree global)
r <- raster()
validCell(r, c(-1, 0, 1))
validRow(r, c(-1, 1, 100, 10000))

validNames Create valid names

Description
Create a set of valid names (trimmed, no duplicates, not starting with a number).

Usage
validNames(x, prefix='layer')

Arguments
x character
prefix character string used if x is empty

Value
character

See Also
make.names
Examples
validNames(c('a', 'a', '', '1', NA, 'b', 'a'))

weighted.mean Weighted mean of rasters

Description
Computes the weighted mean for each cell of a number or raster layers. The weights can be spatially variable or not.

Usage
## S4 method for signature 'RasterStackBrick,vector'
weighted.mean(x, w, na.rm=FALSE, filename='', ...)

## S4 method for signature 'RasterStackBrick,RasterStackBrick'
weighted.mean(x, w, na.rm=FALSE, filename='', ...)

Arguments
x RasterStack or RasterBrick
w A vector of weights (one number for each layer), or for spatially variable weights, a RasterStack or RasterBrick with weights (should have the same extent, resolution and number of layers as x)
na.rm Logical. Should missing values be removed?
filename Character. Output filename (optional)
... Additional arguments as for writeRaster

Value
RasterLayer

See Also
Summary-methods, weighted.mean

Examples
b <- brick(system.file("external/rlogo.grd", package="raster"))

# give least weight to first layer, most to last layer
wm1 <- weighted.mean(b, w=1:3)

# spatially varying weights
# weigh by column number
w1 <- init(b, v='col')

```r
# weigh by row number
w2 <- init(b, v='row')
w <- stack(w1, w2, w2)
wm2 <- weighted.mean(b, w=w)
```

### Description

Which returns a RasterLayer with TRUE or FALSE setting cells that are NA to FALSE (unless na.rm=FALSE). If the RasterLayer has numbers, all values that are 0 become FALSE and all other values become TRUE. The function can also return the cell numbers that are TRUE.

### Usage

```r
## S4 method for signature 'RasterLayer'
Which(x, cells=FALSE, na.rm=TRUE, ...)
```

### Arguments

- `x` RasterLayer
- `cells` logical. If TRUE, cell numbers are returned, otherwise a RasterLayer is returned.
- `na.rm` logical. If TRUE, NA values are treated as FALSE, otherwise they remain NA (only when cells=FALSE).
- `...` Additional arguments (none implemented).

### Value

RasterLayer

### See Also

`which.max`, `which.min`

### Examples

```r
r <- raster(ncol=10, nrow=10)
set.seed(0)
r[] <- runif(ncell(r))
r[r < 0.2 ] <- 0
r[r > 0.8] <- 1
r[r > 0 & r < 1 ] <- 0.5
Which(r, cells=TRUE)
Which(r > 0.5, cells=TRUE)
```
```r
s1 <- r > 0.5
s2 <- Which(r > 0.5)
s1[1:15]
s2[1:15]

# this expression
x1 <- Which(r, na.rm=FALSE)
# is the inverse of
x2 <- r==0
```

### Description

Which cells have the minimum / maximum value (for a RasterLayer), or which layer has the minimum/maximum value (for a RasterStack or RasterBrick)?

which.min and which.max return the index of the first layer that has the min or max value for a cell. This can be problematic if there are ties.

In you want the index of all the layers that have the min or max value, use whiches.min or whiches.max (only for objects with less than 10 layers).

### Usage

```r
which.min(x)
which.max(x)
whiches.min(x, ...)
whiches.max(x, ...)
```

### Arguments

- `x` Raster* object
- `...` additional arguments (none implemented)

### Value

(which.*): vector of cell numbers (if x is a RasterLayer). If x is a RasterStack or RasterBrick, a RasterLayer giving the number of the first layer with the minimum or maximum value for a cell.

(whiches.*): An integer in which each digit represents a layer. For example, 35 means "layers 3 and 5"

### Note

There is a limit to accurate integer number representation. Therefore, do not use whiches.* with more than 15 layers.
writeFormats

Which

Examples

b <- brick(system.file("external/rlogo.grd", package="raster"))

r <- which.min(b)

i <- which.min(b[[3]])
xy <- xyFromCell(b, i)
plot(b[[3]])
points(xy)

x <- whiches.min(b)
freq(x)

writeFormats | File types for writing

Description

List supported file types for writing RasterLayer values to disk.
When a function writes a file to disk, the file format is determined by the 'format=' argument if supplied, or else by the file extension (if the extension is known). If other cases the default format is used. The 'factory-fresh' default format is 'raster', but this can be changed using rasterOptions.

Usage

writeFormats()

Details

writeFormats returns a matrix of the file formats (the "drivers") that are supported.
Supported formats include:

<table>
<thead>
<tr>
<th>File type</th>
<th>Long name</th>
<th>default extension</th>
<th>Multiband support</th>
</tr>
</thead>
<tbody>
<tr>
<td>raster</td>
<td>'Native' raster package format</td>
<td>.grd</td>
<td>Yes</td>
</tr>
<tr>

GDALDriver-class

Examples

```r
writeFormats()
```

### writeRaster

**Write raster data to a file**

#### Description

Write an entire Raster* object to a file, using one of the many supported formats. See `writeValues` for writing in chunks (e.g. by row).

When writing a file to disk, the file format is determined by the 'format=' argument if supplied, or else by the file extension (if the extension is known). If other cases the default format is used. The default format is 'raster', but this setting can be changed (see `rasterOptions`).

#### Usage

```r
## S4 method for signature 'RasterLayer,character'
writeRaster(x, filename, format, ...)

## S4 method for signature 'RasterStackBrick,character'
writeRaster(x, filename, format, bylayer, suffix='numbers', ...)
```

#### Arguments

- **x**: Raster* object
- **filename**: Output filename
- **format**: Character. Output file type. See `writeFormats`. If this argument is not provided, it is attempted to infer it from the filename extension. If that fails, the default format is used. The default format is 'raster', but this can be changed using `rasterOptions`
- **...**: Additional arguments:
  - **datatype**: Character. Output data type (e.g. 'INT2S' or 'FLT4S'). See `dataType`. If no datatype is specified, 'FLT4S' is used, unless this default value was changed with `rasterOptions`
  - **overwrite**: Logical. If TRUE, "filename" will be overwitten if it exists
  - **progress**: Character. Set a value to show a progress bar. Valid values are "text" and "window".
  - **NAflag**: Numeric. To overwrite the default value used to represent NA in a file
  - **bandorder**: Character. 'BIL', 'BIP', or 'BSQ'. For 'native' file formats only. For some other formats you can use the 'options' argument (see below)
writeRaster

options: Character. File format specific GDAL options. E.g., when writing a geotiff file you can use: options=c("COMPRESS=NONE", "TFW=YES")
You can use options=c("PROFILE=BASLINE") to create a plain tif with no GeoTIFF tags. This can be useful when writing files to be read by applications intolerant of unrecognised tags. (see http://www.gdal.org/frmt_gtiff.html)
NetCDF files have the following additional, optional, arguments: varname, varunit, longname, xname, yname, zname, zunit
prj: Logical. If TRUE, the crs is written to a .prj file. This can be useful when writing to an ascii file or another file type that does not store the crs
bylayer if TRUE, write a separate file for each layer. You can provide a vector of filenames that matches the number of layers. Or you can provide a single filename that will get a unique suffix (see below)
suffix 'numbers' or 'names’ to determine the suffix that each file gets when bylayer=TRUE; either a number between 1 and nlayers(x) or names(x)

Details

See writeFormats for supported file types ("formats", "drivers").
The rgdal package is needed, except for these file formats: 'raster', 'BIL', 'BIP', 'BSQ', 'SAGA', 'ascii', 'IDRISI', and 'CDF'. Some of these formats can be used with or without rgdal (idrisi, SAGA, ascii). You need the 'ncdf4' library for the 'CDF' format.
In multi-layer files (i.e. files saved from RasterStack or RasterBrick objects), in the native 'raster' format, the band-order can be set to BIL (’Bands Interleaved by Line’), BIP (’Bands Interleaved by Pixels’) or BSQ (’Bands SeQuential’). Note that bandorder is not the same as filetype here.
Supported file types include:

<table>
<thead>
<tr>
<th>File type</th>
<th>Long name</th>
<th>default extension</th>
<th>Multiband support</th>
</tr>
</thead>
<tbody>
<tr>
<td>raster</td>
<td>'Native' raster package format</td>
<td>.grd</td>
<td>Yes</td>
</tr>
<tr>
<td>ascii</td>
<td>ESRI Ascii</td>
<td>.asc</td>
<td>No</td>
</tr>
<tr>
<td>SAGA</td>
<td>SAGA GIS</td>
<td>.sdat</td>
<td>No</td>
</tr>
<tr>
<td>IDRISI</td>
<td>IDRISI</td>
<td>.rst</td>
<td>No</td>
</tr>
<tr>
<td>CDF</td>
<td>netCDF (requires ncdf4)</td>
<td>.nc</td>
<td>Yes</td>
</tr>
<tr>
<td>GTiff</td>
<td>GeoTiff (requires rgdal)</td>
<td>.tif</td>
<td>Yes</td>
</tr>
<tr>
<td>ENVI</td>
<td>ENVI .hdr Labelled</td>
<td>.envi</td>
<td>Yes</td>
</tr>
<tr>

<td>ESR1 .hdr Labelled</td>
<td>.bil</td>
<td>Yes</td>
</tr>
<tr>
<td>HFA</td>
<td>Erdas Imagine Images (.img)</td>
<td>.img</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Value

This function is used for the side-effect of writing values to a file.

See Also

writeFormats, writeValues
Examples

```r
# take a small part
r <- crop(r, extent(179880, 180880, 329880, 330840))

# write to an integer binary file
rf <- writeRaster(r, filename="allint.grd", datatype='INT4S', overwrite=TRUE)

# make a brick and save multi-layer file
b <- brick(r, sqrt(r))
bf <- writeRaster(b, filename="multi.grd", bandorder='BIL', overwrite=TRUE)

# write to a new geotiff file (depends on rgdal)
if (require(rgdal)) {
  rf <- writeRaster(r, filename="test.tif", format='GTiff', overwrite=TRUE)
  bf <- writeRaster(b, filename="multi.tif", options="INTERLEAVE=BAND", overwrite=TRUE)
}

# write to netcdf
if (require(ncdf)) {
  rnc <- writeRaster(r, filename='netCDF.nc', format='CDF', overwrite=TRUE)
}
```

writeValues  Write values to a file

Description

Functions for writing blocks (>= 1 row(s)) of values to files. Writing has to start at the first cell of a row (identified with argument `start`) and the values written must represent 1 or more entire rows. Begin by opening a file with `writestart`, then write values to it in chunks. When writing is done close the file with `writestop`.

If you want to write all values of a Raster* object at once, you can also use `writeRaster` which is easier to use but more limited. The functions described here allow writing values to file using chunks of different sizes (e.g. 1 or 10 rows). Function `blockSize` can be used to suggest a chunk size to use.

Usage

- `writeStart(x, filename, ...)`
- `writeValues(x, v, start)`
- `writeStop(x)`
### writeValues

**Arguments**

- **x**: Raster* object
- **filename**: character. Output file name
- **...**: additional arguments as for writeRaster
- **v**: vector (RasterLayer) or matrix (RasterBrick) of values
- **start**: Integer. Row number (counting starts at 1) from where to start writing v

**Value**

RasterLayer or RasterBrick

**See Also**

writeRaster, blockSize, update

**Examples**

```r
r <- raster(system.file("external/test.grd", package="raster"))
# write to a new binary file in chunks
s <- raster(r)
#
tr <- blockSize(r)
tr
s <- writeStart(s, filename='test.grd', overwrite=TRUE)
for (i in 1:tr$n) {
  v <- getValuesBlock(r, row=tr$row[i], nrows=tr$nrows[i])
  s <- writeValues(s, v, tr$row[i])
}s <- writeStop(s)

if(require(rgdal)){
  s2 <- writeStart(s, filename='test2.tif', format='GTiff', overwrite=TRUE)
  # writing last row first
  for (i in tr$n:1) {
    v <- getValuesBlock(r, row=tr$row[i], nrows=tr$nrows[i])
    s2 <- writeValues(s2, v, tr$row[i])
  }
  # row number 5 once more
  v <- getValuesBlock(r, row=5, nrows=1)
  writeValues(s2, v, 5)
  s2 <- writeStop(s2)
}

## write values of a RasterStack to a RasterBrick
s <- stack(system.file("external/rlogo.grd", package="raster"))
# create empty brick
b <- brick(s, values=FALSE)
b <- writeStart(b, filename="test.grd", format="raster", overwrite=TRUE)
```
tr <- blockSize(b)
for (i in 1:tr$n) {
  v <- getValuesBlock(s, row=tr$row[i], nrows=tr$nrows[i])
  b <- writeValues(b, v, tr$row[i])
}
b <- writeStop(b)
# note that the above is equivalent to
# b <- writeRaster(s, filename="test.grd", format="raster", overwrite=TRUE)

xyFromCell

Coordinates from a row, column or cell number

Description
These functions get coordinates of the center of raster cells for a row, column, or cell number of a Raster* object.

Usage

xFromCol(object, col=1:ncol(object))
yFromRow(object, row=1:nrow(object))
xyFromCell(object, cell, spatial=FALSE)
xFromCell(object, cell)
yFromCell(object, cell)

Arguments

Object: Raster* object (or a SpatialPixels* or SpatialGrid* object)

Cell: cell number(s)

Col: column number; or vector of column numbers

Row: row number; or vector of row numbers

Spatial: return a SpatialPoints object (sp package) instead of a matrix

Details
Cell numbers start at 1 in the upper left corner, and increase from left to right, and then from top to bottom. The last cell number equals the number of cells of the Raster* object.

Value

xFromCol, yFromCol, xFromCell, yFromCell: vector of x or y coordinates

xyFromCell: matrix(x,y) with coordinate pairs

See Also
cellFromXY
Examples

```r
# using a new default raster (1 degree global)
r <- raster()
xFromCol(r, c(1, 120, 180))
yFromRow(r, 90)
xyFromCell(r, 10000)
xyFromCell(r, c(0, 1, 32581, ncell(r), ncell(r)+1))

# using a file from disk
r <- raster(system.file("external/test.grd", package="raster"))

r
cellFromXY(r, c(180000, 330000))
# xy for corners of a raster:
xyFromCell(r, c(1, ncol(r), ncell(r)-ncol(r)+1, ncell(r)))
```

---

### z-values

#### Get or set z-values

Description

Initial functions for a somewhat more formal approach to get or set z values (e.g. time) associated with layers of Raster* objects. In development.

Usage

```r
setZ(x, z, name='time')
getZ(x)
```

Arguments

- **x**: Raster* object
- **z**: vector of z values of any type (e.g. of class 'Date')
- **name**: character label

Value

- **setZ**: Raster* object
- **getZ**: vector

Examples

```r
r <- raster(ncol=10, nrow=10)
s <- stack(lapply(1:3, function(x) setValues(r, runif(ncell(r)))))
s <- setZ(s, as.Date("2000-1-1") + 0:2)
s
getz(s)
```
Description

Experimental function to apply a function over a (time) series of layers of a Raster object

Usage

\[
zApply(x, \text{by}, \text{fun}=\text{mean}, \text{name}='', \ldots)\]

Arguments

- **x**: Raster* object
- **by**: aggregation indices or function
- **fun**: function to compute aggregated values
- **name**: character label of the new time series
- **...**: additional arguments

Value

Raster* object

Author(s)

Oscar Perpinan Lamigueiro & Robert J. Hijmans

Examples

```r
# 12 values of irradiation, 1 for each month
gOdm=c(2.766,3.491,4.494,5.912,6.989,7.742,7.919,7.027,5.369,3.562,2.814,2.179)*1000;
# RasterBrick with 12 layers based on G0dm + noise
r <- raster(nc=10, nr=10)
s <- brick(lapply(1:12, function(x) setValues(r, gOdm[x]+100*rnorm(nceII(r))))))

# time
tm <- seq(as.Date('2010-01-15'), as.Date('2010-12-15'), 'month')
s <- setZ(s, tm, 'months')

# library(zoo)
# x <- zApply(s, by=as.yearqtr, fun=mean, name='quarters')
```
zonal  

Zonal statistics

Description

Compute zonal statistics, that is summarized values of a Raster* object for each "zone" defined by a RasterLayer.

If stat is a true function, zonal will fail (gracefully) for very large Raster objects, but it will in most cases work for functions that can be defined as by a character argument ('mean', 'sd', 'min', 'max', or 'sum'). In addition you can use 'count' to count the number of cells in each zone (only useful with na.rm=TRUE, otherwise freq(z) would be more direct.

If a function is used, it should accept a na.rm argument (or at least a . . . argument)

Usage

```r
## S4 method for signature 'RasterLayer,RasterLayer'
zonal(x, z, fun='mean', digits=0, na.rm=TRUE, ...)

## S4 method for signature 'RasterStackBrick,RasterLayer'
zonal(x, z, fun='mean', digits=0, na.rm=TRUE, ...)
```

Arguments

- `x` Raster* object
- `z` RasterLayer with codes representing zones
- `fun` function to be applied to summarize the values by zone. Either as character: 'mean', 'sd', 'min', 'max', 'sum'; or, for relatively small Raster* objects, a proper function
- `digits` integer. Number of digits to maintain in 'zones'. By default averaged to an integer (zero digits)
- `na.rm` logical. If TRUE, NA values in x are ignored
- `...` additional arguments. One implemented: progress, as in writeRaster

Value

A matrix with a value for each zone (unique value in zones)

See Also

See cellStats for 'global' statistics (i.e., all of x is considered a single zone), and extract for summarizing values for polygons
Examples

```r
r <- raster(ncols=10, nrows=10)
r[] <- runif(ncell(r)) * 1:ncell(r)
z <- r
z[] <- rep(1:5, each=20)
# for big files, use a character value rather than a function
zonal(r, z, 'sum')

# for smaller files you can also provide a function
## Not run:
zonal(r, z, mean)
zonal(r, z, min)

## End(Not run)

# multiple layers
zonal(stack(r, r*10), z, 'sum')
```

Description

Zoom in on a map (plot) by providing a new extent, by default this is done by clicking twice on the map.

Usage

```r
zoom(x, ...)
## S4 method for signature 'Raster'
zoom(x, ext=drawExtent(), maxpixels=100000, layer=1, new=TRUE, useRaster=TRUE, ...)

## S4 method for signature 'Spatial'
zoom(x, ext=drawExtent(), new=TRUE, ...)

## S4 method for signature 'missing'
zoom(x, ext=drawExtent(), new=TRUE, ...)
```

Arguments

- `x` Raster* or Spatial* (vector type) object
- `ext` Extent object, or other object from which an extent can be extracted
- `maxpixels` Maximum number of pixels used for the map
- `layer` Positive integer to select the layer to be used if `x` is a multilayer Raster object
- `new` Logical. If `TRUE`, the zoomed in map will appear on a new device (window)
- `useRaster` Logical. If `TRUE`, a bitmap raster is used to plot the image instead of polygons
- `...` additional parameters for `plot`
zoom

Value

Extent object (invisibly)
