

Package ‘monographaR’

October 11, 2020

Version 1.2.1

Date 2020-10-09

Title Taxonomic Monographs Tools

Author Marcelo Reginato

Maintainer Marcelo Reginato <reginatobio@yahoo.com.br>

Depends R (>= 3.5.0), maptools

Suggests knitr

Imports circular, png, raster, rmarkdown, sp

Description Contains functions intended to facilitate the production of plant taxonomic monographs. The package includes functions to convert tables into taxonomic descriptions, lists of collectors, examined specimens, and can generate a monograph skeleton. Additionally, wrapper functions to batch the production of phenology charts and distributional and diversity maps are also available.

buildMonograph	<i>Build and export a monograph skeleton (draft)</i>
----------------	--

Description

This function will generate a MS-Word or html file with a monograph skeleton (draft)

Usage

```
buildMonograph(headings, tableToDescription.data, examinedSpecimens.data = NULL,
collectorList.data = NULL, output = "Word", title = "Taxonomic treatment",
open = TRUE)
```

Arguments

headings	data.frame
tableToDescription.data	data.frame
examinedSpecimens.data	data.frame (optional)
collectorList.data	data.frame (optional)
output	"Word" or "html"
title	character
open	logical

Details

This function wraps around the functions `tableToDescription`, `examinedSpecimens` and `collectorList` generating a monograph draft in MS-Word or html format. The resulting monograph skeleton will include the taxonomic heading, the description, comments and examined specimens list for all species found in the input tables, and it will append the collector list in the end of the file. It requires four tables as input. Three of them are the same tables used for `tableToDescription`, `collectorList`, and `examinedSpecimens` functions. The additional input table should have three columns: species, taxonomic heading and comments. The `examinedSpecimens.data` and `collectorList.data` tables are optional. It uses functions of the `rmarkdown` package to export the output file.

Value

Exports a file (MS-Word or html).

Author(s)

Marcelo Reginato

See Also[rmarkdown](#)**Examples**

```
data(monographaR_examples)
monographaR_examples$taxonomic_headings -> taxonomic.headings
monographaR_examples$collectorList -> col.d
monographaR_examples$examinedSpecimens -> exam.d
monographaR_examples$tableToDescription -> desc.d
desc.d[, -1] -> desc.d

### buildMonograph(headings=taxonomic.headings,
###                 collectorList.data = col.d,
###                 examinedSpecimens.data = exam.d,
###                 tableToDescription.data = desc.d,
###                 output = "Word", title="Monograph skeleton")
```

collectorList	<i>Generates a collector list</i>
---------------	-----------------------------------

Description

This function will generate a txt file with a collector list for all species in data.

Usage

```
collectorList(data = data, filename = "collector_list.txt",
              paragraphs = TRUE)
```

Arguments

data	data.frame
filename	character
paragraphs	logical

Details

It requires a data.frame with five columns, ordered as species, collector name, collector number, herbarium acronym and herbarium number. Herbarium columns are only used if any collector number is missing (NA). Thus, if there is no missing values in collector number, then the herbarium columns might be empty.

Value

Exports a txt file.

Author(s)

Marcelo Reginato

Examples

```
## loading the example data

data(monographaR_examples)
monographaR_examples$collectorList -> data
head(data)

## running the function, it will print in the terminal the output.
## To export a txt, place a ## name in the filename argument
## (i.e., filename = "myoutput.txt")

collectorList(data, filename = "", paragraphs = TRUE)

## or a second option

collectorList(data, filename = "", paragraphs = FALSE)
```

examinedSpecimens *Generates an examined specimens list*

Description

This function will generate a txt file with an examined specimens list.

Usage

```
examinedSpecimens(data, filename = "examined.txt")
```

Arguments

data	data.frame
filename	character

Details

It requires a data.frame with eight columns, ordered as: species, collector name, collector number, herbarium acronym, herbarium number, country, state and municipality.

Value

Exports a txt file.

Author(s)

Marcelo Reginato

Examples

```
## loading the example data

data(monographaR_examples)
monographaR_examples$examinedSpecimens -> data
head(data)

## running the function, it will print in the terminal the output.
## To export a txt, place a name in the filename argument
## (i.e., filename = "myoutput.txt")

examinedSpecimens(data, filename = "")
```

mapBatch*Generates map in batch mode*

Description

This wrapper function will export maps for all species in data.

Usage

```
mapBatch(data, zoom = T, margin = 0.1, axes = T, shape = NULL,
export = "pdf", raster = NULL, RGB = NULL, points.col = "black",
points.border = "gray50", points.cex = 1, shape.col = "white",
shape.border = "black", raster.col = rev(gray.colors(65, start = 0, end = 1)),
raster.legend = F, hillshade = F, width = 8, height = 8,
image.resolution = 100, figure.number = T, title = T, box = T,
add.minimap = F, minimap.shape = NULL, minimap.shape.col = "white",
minimap.shape.border = "gray50", minimap.pos = "topleft",
minimap.add.points = T, minimap.points.col = "black",
minimap.points.border = "gray50", minimap.points.cex = 1,
minimap.extent = NULL, minimap.rect.fill = NA, minimap.rect.border = NULL,
maxpixels = 1e+05, ...)
```

Arguments

data	data.frame
zoom	logical
margin	numeric
axes	logical

shape	a single or a list of spatial shape objects
export	"pdf", "jpeg" or "tiff"
raster	a raster object
RGB	a raster stack object (with three layers)
points.col	character
points.border	character
points.cex	numeric
shape.col	character
shape.border	character
raster.col	character (a vector of colors)
raster.legend	logical
hillshade	logical
width	numeric (in inches)
height	numeric (in inches)
image.resolution	numeric
figure.number	logical
title	logical
box	logical
add.minimap	logical
minimap.shape	a spatial shape object
minimap.shape.col	character (color)
minimap.shape.border	character (color)
minimap.pos	"topleft", "topright", "bottomleft" or "bottomright"
minimap.add.points	logical
minimap.points.col	character (color)
minimap.points.border	character (color)
minimap.points.cex	numeric
minimap.extent	numeric (x1, x2, y1, y2)
minimap.rect.fill	character (color)
minimap.rect.border	character (color)
maxpixels	numeric
...	additional arguments for plotting the extra shapes

Details

The function has three output options: a single pdf with all maps (`export = "pdf"`) or individual image files for each species (`export = "tiff"` or `"jpeg"`). It requires a `data.frame` with three columns, ordered as: `species`, `longitude` and `latitude`. If `zoom = TRUE`, the function will set the limits of the plot using the distribution of each species plus the margin (relative value). If `zoom = FALSE`, the function will use the distribution of the whole data to set the limits (all maps will have the same limits). Colors can be changed with the arguments `points.col`, `shape.col`, `shape.border`, while the size of the points can be changed with `points.cex`. A raster layer can be provided (elevation for instance), and the colors of the raster are controlled by `raster.col`. The user can provide a single or a list of shape files, otherwise the `maptools` map is used.

Value

Exports a pdf or image files.

Author(s)

Marcelo Reginato

[maptools raster](#)

Examples

```
## loading the example data

data(monographaR_examples)
monographaR_examples$map_data -> data
head(data)

## running the function

# mapBatch(data , type="simple", zoom=T, margin=0.2, points.col="black",
# points.border="white", shape.col="gray90", points.cex=1.5, shape.border
# = "gray90", export="pdf")
```

mapDiversity

Diversity heatmap

Description

This function will generate a diversity heatmap using presence/absence of species on grid cells.

Usage

```
mapDiversity(data, resolution = 1, plot = T, plot.with.grid = T,  
col=rev(terrain.colors(55)), alpha=0.8, export = F, legend = T,  
filename = "diversity_map")
```

Arguments

data	data.frame
resolution	numeric, size of the grid cells (degrees)
plot	logical
plot.with.grid	logical, whether or not to add a grid to the plot
col	character, a vector of colors
alpha	numerical, controls color transparency (0-1)
export	logical
legend	logical
filename	character

Details

It requires a data.frame with three columns, ordered as: species, longitude and latitude. The function will plot and return a raster object. The resolution of the grid can be changed by the argument "resolution" (in degrees). It uses functions of the package raster.

Value

A raster object.

## running the function  
  
mapDiversity(data , resolution=1, plot=TRUE, plot.with.grid=TRUE)
```

```

## Without the grid borders
mapDiversity(data , resolution=1, plot=TRUE, plot.with.grid=FALSE)

## Changing colors
mapDiversity(data , resolution=1, plot=TRUE, col=gray.colors(55))

## Changing transparency
mapDiversity(data , resolution=1, plot=TRUE, alpha=0.5)

## The function returns a raster object
mapDiversity(data , resolution=1, plot=TRUE, alpha=0.5) -> my.div.raster
my.div.raster
plot(my.div.raster)

```

mapPhenology

Phenology heatmap

Description

This function will generate phenology maps across time (month, week, etc..).

Usage

```

mapPhenology(data, resolution = 1, time.range = c(1:12), label = "Month",
binary = T, by_species = F, plot = T, col = rev(heat.colors(12)),
alpha = 0.8, mfrow = c(4, 3), legend = T, pdf = F, height = 11,
width = 8.5, filename = "mapPhenology.pdf")

```

Arguments

data	data.frame
resolution	numeric (degrees)
time.range	numeric (vector of months, weeks, etc...)
label	character ("Month", "Week")
binary	logical
by_species	logical
plot	logical
col	character (vector of colors)
alpha	numeric (0-1)
mfrow	numeric

legend	logical
pdf	logical
height	numerical
width	numerical
filename	character

Details

This wrapper function will generate heatmaps of phenology across a time range. The default is to produce 12 heatmaps plotted on a single plate. This can be changed with the argument `time.range`, where any numerical range can be provided (representing weeks for instance). The argument `mfrow` controls the plate layout. It requires a `data.frame` with four columns, ordered as: species, longitude, latitude and phenology. The phenology column should be numeric (i.e., the number of the month, week or day the specimen was collected with flower/fruit). It is possible to change the resolution of the resulting rasters. The function can produce presence/absence heatmaps (if `binary = T`) or abundance heatmaps (if `binary = F`). The abundance values are relative (divided by the maximum abundance observed across all rasters). The function returns a `RasterStack` that can be exported or used in customized plots. To export a pdf, set `"pdf=TRUE"`. The function wraps around functions of the raster package.

Value

`RasterStack`

Examples

```
### load the example data

data(monographaR_examples)
monographaR_examples$mapPhenology -> data
head(data) ## check the first rows

### running the function

# mapPhenology(data, binary=FALSE, by_species=FALSE, legend=FALSE)

### changing the colors

# mapPhenology(data, binary=FALSE, by_species=FALSE, legend=FALSE, col=rev(terrain.colors(55)))

### exporting raster
```

```

# require(raster)
# mapPhenology(data, binary=FALSE, by_species=FALSE, legend=FALSE) -> myphenorasters
# plot(myphenorasters[[1]]) ## plot first month
# writeRaster(myphenorasters[[2]], "pheno_month2.asc") ## exporting 2nd month

### making an GIF animation

# require(animation)
# saveGIF(
# {mapPhenology(data, binary=F, resolution=0.5, by_species=F, legend=F, mfrow=c(1,1))},
# movie.name="phenology.gif", interval=0.5, ani.width=600, ani.height=600
# )

```

mapTable	<i>Generates a presence/absence matrix of species on grids or countries</i>
----------	---

Description

This function will generate a presence/absence matrix based on a grid (if type="grid") or on countries (if type="countries").

Usage

```
mapTable(data, type = "grid", resolution = 1, pres.abs = TRUE,
write.output = FALSE, layer = NULL)
```

Arguments

data	data.frame
type	"grid", "countries" or "user"
resolution	numeric (degrees)
pres.abs	logical
write.output	logical
layer	Spatial DataFrame object, see readShapeSpatial

Details

It requires a data.frame with three columns, ordered as: species, longitude and latitude. The resolution of the grid can be changed by the argument "resolution" (in degrees). If type = "user", a layer to intersect the points and create the matrix should be supplied (a Spatial DataFrame object). It uses functions of the package raster and maptools. If pres.abs = F the returned matrix will have "x" instead of 0 and 1.

Value

list, with a matrix and grid (if type="grid"), or a matrix (if type="countries").

monographaR_examples *Input data examples*

Description

Input table examples. Seven data.frames are listed in this example data set. See help files of the functions for details.

Examples

```
data(monographaR_examples)

names(monographaR_examples)

head(monographaR_examples$colletorList)
head(monographaR_examples$examinedSpecimens)
head(monographaR_examples$phenoHist)
head(monographaR_examples$tableToDescription)
head(monographaR_examples$map_data)
head(monographaR_examples$mapPhenology)
head(monographaR_examples$taxonomic_headings)
```

 phenoHist

Circular histograms of phenology

Description

This wrapper function will generate circular histograms of phenology, using functions of the package `circular`.

Usage

```
phenoHist(data = data, mfrow = c(1, 1), shrink = 1.2, axis.cex =
1.5, title.cex = 1.5, pdf = F, height=11, width=8.5,
filename = "phenology.pdf", flower = "Flower", fruit = "Fruit",
both = "Both", flower.col = NULL, flower.border = "black",
fruit.col = "darkgray", fruit.border = "darkgray", mar=c(2,2,2,2))
```

Arguments

<code>data</code>	data.frame
<code>mfrow</code>	numeric, (nrow, ncol)
<code>shrink</code>	numeric
<code>axis.cex</code>	numeric
<code>title.cex</code>	numeric
<code>pdf</code>	logical
<code>height</code>	numeric
<code>width</code>	numeric
<code>filename</code>	character
<code>flower</code>	character (how is the flower indicated in data, if missing place "missing")
<code>fruit</code>	character (how is the fruit indicated in data, if missing place "missing")
<code>both</code>	character (how is the both indicated in data, if missing place "missing")
<code>flower.col</code>	character (color of flower bars)
<code>flower.border</code>	character (color of flower border bars)
<code>fruit.col</code>	character (color of fruit bars)
<code>fruit.border</code>	character (color of fruit border bars)
<code>mar</code>	numeric (plot margins, vector of 4 values)

Details

It requires a data.frame with three columns, ordered as: species, month and phenology. The month column should be numeric (month number), while the phenology column must have these values: "Flower", "Fruit" and/or "Both". If any of these are missing is possible to indicate in the "flower", "fruit" and "both" arguments (both="missing"). The function will plot the bars indicating flower observations in white, and fruits in gray by default (is possible to change it with the "flower.col", "flower.border", "fruit.col" and "fruit.border" arguments). The size of the bar corresponds to number of observations. The arguments "shrink", "axis.cex" and "title.cex" control sizes, while the "mfrow" changes the number of histograms plotted at the same page (rows, columns).

Value

Exports a pdf file.

Examples

```
## loading the example data

data(monographaR_examples)
monographaR_examples$phenoHist -> data
head(data)

## running the function

phenoHist(data, mfrow=c(2,2), shrink=1.2, axis.cex=1.5, title.cex=1.5,
pdf=FALSE)

## changing the color

phenoHist(data, mfrow=c(2,2), shrink=1.2, axis.cex=1.5, title.cex=1.5,
pdf=FALSE, flower.col=rgb(0.2,1,0.2, 0.5), flower.border=rgb(0.2,1,0.2,
0.5), fruit.col="darkgreen", fruit.border="black")

## plotting only flower (if "fruit" and/or "both" information are
## missing for instance)

phenoHist(data, mfrow=c(2,2), shrink=1.2, axis.cex=1.5, title.cex=1.5,
pdf=FALSE, fruit="missing", both="missing", flower.col="red",
flower.border="darkgray")
```

tableToDescription	<i>Generates species descriptions</i>
--------------------	---------------------------------------

Description

This function will generate a txt file with species descriptions.

Usage

```
tableToDescription(data, filename = "species_descriptions.txt")
```

Arguments

data	data.frame
filename	character

Details

It requires a data.frame where the first three columns are the character description, putative complement and the character to use as separator (i.e., words that will remain constant across descriptions). The character description and/or the complement might be empty. The remaining columns are the species with their respective character states, where each row is a character. The function accepts any number of species and/or characters.

Value

Exports a txt file

Author(s)

Marcelo Reginato

Examples

```
## loading the example data

data(monographaR_examples)
monographaR_examples$tableToDescription -> data
head(data)

## the first column is just an identifier for the characters, we need to
## remove it before running the analysis

data[,-1] -> data

## running the function, it will print in the terminal the output.
## To export a txt, place a name in the filename argument
## (i.e., filename = "myoutput.txt")
```

```
tableToDescription(data, filename = "")
```
